# SCIENTIFIC AND INDUSTRIAL RESEARCH.—III

IN the conception of the strategy of research which we have thus far developed, the first place has been given to the supply of research workers of the type required to serve the needs of the broad programmes of research contemplated. We have stressed the need for creative and imaginative minds, and in considering the functions of the universities in training such workers, it was recognized that while specialists are essential they may have to take their place in team-work, and that freedom of research requires that the specialist should be competent to move freely across the compartments of science which are at present imposed by the teaching and organization of science. Further, it was recognized that provision must be made to assist in bringing to the fore directors or managers of research of the requisite calibre.

We have now to consider more fully the tactics by which these requirements can be further fostered and developed. Admittedly, in referring to the question of leadership, we have already entered the domain of tactics: the provision of senior fellowships of research is a matter of tactics, whether we view it from the point of view of facilities and organization for research or of encouraging the development of men of the right type for responsible positions in the direction of research. There are, however, two points to be noted here before proceeding to consider the question of tactics in general.

It is, however, no part of the strategy of research to provide directly for the leaders required, any more than it is the function of the universities. It is necessary to emphasize this in view of the tendencies in the recent report of the British Association Committee on Post-war University Education and elsewhere to suggest that the universities are forcing-houses for leaders, either in industry or in other spheres. It is true that it is desirable that a larger proportion of the leaders of industry, for example, should spring from those whose training qualifies them to appreciate and appraise the scientific or technical factors in a situation or problem. It is true that the training the honours graduate in science receives takes little cognizance of such matters as social and ethical values. To urge that this situation should be improved, however, is not to suggest that the universities should change their functions or that they should depart from their tradition of imparting exact scholarship, and training those skilled in the special knowledge and technique that scholarship demands. It is to urge that such training should be based on a wider education, and that the educational system should be such that there are no impediments to originality and to those who possess creative and imaginative minds. It is with education at the pre-university level that we are concerned here, and this is the aspect that brings the educational system and policy of the country as a whole into the purview of research strategy. There could be no more fatal blunder than to introduce into the selection of scholars for the universities other

considerations than those of intellectual ability, originality and independence of mind, so far as these can be assessed.

We would not imply that character is not important. Rather, if the conditions at university and secondary school are right, it will be developed as a matter of course. But its selective influence will make itself felt when the graduate enters the larger world, in so far as its importance is recognized by the community, just as physical fitness is recognized as important. We cannot tolerate conditions at the universities of Britain which would lower the moral and physical standards of the community, and it is right that in our replanning of the universities, past neglect should be repaired. But it remains true that their prime preoccupation should be with the training of the mind and with the maintenance of high intellectual standards, not of mere book learning, but of scholarship, the capacity to think clearly, to weigh evidence, to handle knowledge effectively.

Granted then that the educational system of Britain has been re-organized and the university system expanded to provide industry and the nation as a whole with the right type of men and women for positions of research, administration and production adequate to the present needs, we have to consider next the tactics by which both the supply and the quality are to be maintained. These are the matters with which in the main the recent statement from Nuffield College is concerned, though a good deal of the same ground is covered by the subsequent report of the Association of Scientific Workers.

The first point to which attention should be directed here is that which has been repeatedly emphasized since the debates on scientific research in the House of Lords last year. If we are to be assured of an adequate supply of the right type of men and women for research and for like positions where scientific knowledge is required, the conditions of service must be sufficiently attractive. This must apply not merely to positions in industry and in Government departments but also in the universities themselves. The close relation between research and teaching in the universities, which has rightly been stressed, means that there must be a reasonable balance between standards of remuneration and status in both teaching and research posts. Again, from the point of view of research itself, maintenance of the highest standards of teaching makes it essential that the salaries and status of university teaching appointments should compare favourably enough with conditions elsewhere to attract to such work a sufficient proportion of the ablest minds of each generation.

These points are well brought out in the Nuffield College statement, which in general terms supports the more specific proposals which have been advanced by the Association of University Teachers and the Association of Scientific Workers for regrading and for a more adequate scale of salaries for university appointments. Improvement of the low standards which at present obtain in university appointments in this respect is in fact now generally recognized as a tactical measure of the first importance, but the magnitude of the scales must be determined as part of a general policy of rendering a scientific career, especially in research, more attractive. Nor can we separate consideration of salary scales from the consideration of other conditions which affect the attractiveness of a scientific career to men of outstanding ability.

Other conditions may also be considered broadly both from this point of view of making the career of research or of teaching sufficiently attractive to the best minds of each generation, and from the other point of view of making the best possible use of such ability when a scientific career has been chosen. Failure to attend to this second aspect would in fact not only soon render such careers less attractive to the ablest workers and adversely affect recruitment but would also lead to the steady loss of such workers by transfer to other occupations which they found more congenial and where their ability had fuller scope. For this reason it is important that the immediate demands for research workers, and the necessity for increasing university staffs so as to ensure that they have adequate time for teaching and for research, particularly in the newer universities, as the Nuffield College statement notes, should not lead us to overlook the question of keeping some reasonable balance between supply and demand. Violent fluctuations in this respect, with consequent intermittent and perhaps widespread graduate unemployment, can have a very detrimental effect on recruitment. The dangers in this respect to which Mannheim has directed attention and which were stressed again by Mr. Roy Glenday in his recent book should not be ignored. Some attempt on the part of industry and of other institutions to formulate as quantitatively as possible over a period of years the requirements for scientific and other academically trained personnel would be a tactical measure of first-class importance.

It has been recognized elsewhere that there is waste of scientific ability because of its deflexion to administrative or other duties which might be carried out by others not possessed of the same order of scientific ability. The report of the Association of Scientific Workers rightly directs attention to the handicap which an inadequate staff of laboratory technicians may place upon the research worker at the universities. It should be a cardinal point in our post-war short-term policy at least to see that the training of a sufficient number of such technicians is expedited so as to secure the fullest possible use of the services of the first-class scientific ability already available in our research laboratories both in the universities and elsewhere.

This point was particularly well put by the Parliamentary and Scientific Committee in its report on "Scientific Research and the Universities in Post-War Britain". The Nuffield College statement, however, makes the further point that apart from the necessary increase in trained scientific personnel —which may be a process occupying a considerable time—much more could fruitfully be spent in equipping existing research workers with more adequate resources, and high priority should be given to this. Proposals regarding technical services advanced by the Association of Scientific Workers in respect of

the larger universities obviously represent a need by no means confined to the universities themselves.

Equipment for research, either at the universities or elsewhere, is not only a matter of priority, but may well prove a matter enforcing co-operation and co-ordinated planning of research at the universities and at centralized research institutes of the type of the Massachusetts Institute of Technology, as Sir Alfred Egerton has urged.

Here, however, we are concerned primarily with questions of personnel. Next to questions of adequate remuneration and equipment may be placed those of status. It is important to remember that if we would avoid the waste of scientific ability on administrative duties, which in point of fact a research worker of outstanding ability may be ill-qualified to discharge, this is not to imply that his status as a scientific man should be regarded as a bar to promotion to administrative positions. It is of the utmost importance that there should be no such disqualification where a scientific worker shows himself possessed of high administrative ability; but it is equally important that means should be found of encouraging the outstanding research worker while he continues to do the research for which he is best qualified, without wasting that ability by transferring him to a position of higher status in which his ability is less effectively used.

Closely linked to this question of status is that of freedom of investigation and of publication. It is for such exceptional men that it is important to preserve the maximum freedom of investigation which Prof. A. E. Trueman stresses in "Science and the Future". It is worth considering whether, and if so, in what ways, the outstanding investigator might not be rewarded by the higher responsibility which is implied by allowing him to choose his own problem and tackle it in his own way.

The question of publication may be equally important, though this has received less attention except perhaps in the report of the Federation of British Industries Industrial Research Committee. But apart from the question of status or incentive, which is bound up with this question, publication of the scientific aspects of a research is important from the point of view of research itself as well as of the scientific worker. The advancement of science depends on the fullest possible publication of research, and Lord McGowan's words on this point in his address on "The Future of the Chemical Industry" last October are particularly welcome, in view of the contrast in this respect between the practice and outlook of industry in Great Britain and in the United States. Strong support for a more liberal policy of publication has also been forthcoming from Mr. Samuel Courtauld, who advocates the maximum degree of publication consistent with reasonable safeguards against abuse as the best policy for accelerating the healthy growth of every industry based on applied science. Such a policy would simultaneously remove the disadvantage of scientific workers in industry to which Lord McGowan referred, and to that extent increase the attractiveness of an industrial career in research.

Thus far we have been considering conditions of service mainly from the point of view of making a scientific career, especially in research, as attractive as possible to the ablest workers. We have now to consider factors which will promote the most favourable conditions for creative work, and will maintain or even enhance the originality and individuality which we have been at pains to recruit. The value for this purpose of close contact between teaching and research has been recognized, and much the same considerations apply to the promotion of closer relations between research workers in academic and industrial research.

Interchange and mobility of research workers is an invaluable stimulant to freshness of outlook and new ideas, and the Nuffield College statement devotes an important section to the consideration of this problem. Increase in the mobility of research workers, whether between one branch of industry and another, or between industry and the universities or Government departments or vice versa, is not only essential to ensure the best possible distribution of the available supply of research workers, but is also a stimulant to creative thought and the corporate attack on common problems, and especially borderline problems, the value of which it is almost impossible to estimate. Moreover, it is important to note that this should be a two-way traffic. As the Nuffield College statement indicates, there should be systematic provision for research workers engaged in industry to return to the university or to spend a period at a specialized research centre, both to keep their fundamental equipment up to date and to derive refreshment from day-to-day contact with colleagues engaged in other fields of research.

The senior fellowships in science established by Imperial Chemical Industries, Ltd., are one means by which such interchange may be fostered. Joint research councils of the type recently established by the University of Manchester and the Manchester Chamber of Commerce may well develop other means for associating industrial research workers with their local university colleagues. Clearly such measures must also bring academic workers into closer contact with the industries most closely allied to their special branches of work.

The adjustment of conditions of work so that they are more comparable in the different fields is one means of facilitating such mobility and interchange; but one of the most important is the institution of a common system of superannuation, as the Nuffield College statement suggests. Such a system, applying to research workers in all types of institutions, including workers in universities, Government research stations and research associations, technical colleges and polytechnics and scientific workers employed in industry, would, by the adjustment of existing methods of superannuation, make it possible for research workers to move from university work to industry, or to work under Government or a local authority, or vice versa, without any loss of pension rights. Extension of this system to cover the countries of the British Empire would facilitate the interchange of scientific men over the Empire as a whole,

while clearly such arrangements as those between the Imperial College of Science and Technology and the Massachusetts Institute of Technology for the regular interchange of staff and postgraduate students should be encouraged in this and in every possible way.

One such means, particularly at the universities, is the sabbatical year recommended by the University Grants Committee, as enabling scientific workers to give undivided attention to research problems for a long period or to travel and exchange experience with colleagues in other laboratories at home and abroad. This principle is strongly supported by the Association of Scientific Workers in its recent report; and it was noted as one for inquiry by Sir Ernest Simon in his pamphlet on the "Development of British Universities". That was also the note struck by Bruce Truscot in a suggestive discussion of the whole question in which he suggested that adoption of such a project might be premature until some other academic and financial reforms had been effected. The importance of timing in tactics should never be overlooked; but in the meantime, in addition to suggesting that, as a privilege, leave of absence might be asked for and given much more than it is, Bruce Truscot indicates two directions in which the practice might be extended. First, exchange professorships, both within the British Isles and between Great Britain, the Dominions and the United States should be encouraged and so far as possible arranged by a central organization representing the whole of the British universities. Secondly, he suggests the granting of leave purely for purposes of original work and investigation, subject to adequate control.

The second suggestion, in particular, is one that should also be explored by Government departments and by industry, for there is no room for doubt as to the value of such interchanges and wider contacts. There is, however, a further point in regard to the easier interchange between industry and the universities discussed in the Nuffield College statement which deserves to be noted. This is concerned with the subjects of investigation in such interchange between industry and the universities, and bears particularly on the question of freedom of science and of publication. It is argued by some that universities should avoid all association with industrial research of which the results cannot be freely published and made generally available. This attitude is taken up in regard to work being done wholly or partly in a university laboratory, both on the ground that scientific work at the university ought to be carried on without any profit motive and that secrecy always interferes with the free interchange of ideas among the research workers, and creates the wrong atmosphere both for fully successful fundamental research and for teaching.

If that objection is well founded, it merits serious attention in this connexion, for the whole object of our tactics is to create the atmosphere in which research can be most fruitfully carried on and in which originality and creative thought are fostered. It is plainly undesirable, as the Nuffield College statement points out, that the universities, the primary task of which is to combine disinterested research designed for the advancement of knowledge with teaching work of a high standard, should to any considerable extent allow themselves to be diverted to work which they would not undertake on its own merits. That may be unlikely to happen, but it is against the interests of industry itself to allow the fundamental research at the universities to be neglected or impeded.

It is therefore necessary from the point of view of personnel as well as of organization to exercise caution in using university laboratories or research workers for applied research which would involve any restrictive conditions or slackening in the pursuit of science. The danger may perhaps be overstressed. It should be possible to second a university research worker for such work for a period, as difficulties are fewer when the work is not undertaken in a university laboratory. Moreover, while it is right to guard against the danger of university departments falling too much under the influence of particular firms or industries, to the detriment of their main tasks, we must not limit the pursuit of applied science in university institutions where this arises naturally out of the more fundamental work and can be carried on with full freedom to discuss the problems and to publish the results.

Possibly the best solution of this problem will be found along the lines suggested by the Nuffield College statement. If there were a general code of conduct recognized as applicable to university scientific workers undertaking outside industrial work for private firms, it would be a comparatively easy matter to work out a special code to cover these problems. With easier interchange between the different branches of research and a clear code of professional conduct, transfers would present far fewer difficulties than in the past, and a two-way traffic between the universities and industry could be fruitfully established without some of the professional complications which at present arise.

The entire problem is obviously one to be tackled jointly by the universities, professional associations and industrialists, and it is one in which the initiative might well come from the professional associations of scientific workers. Indeed, it would be difficult to exaggerate the importance of the contribution which such associations might make in this field of tactics which we have here been considering. Admittedly, the responsibility for executive action will rarely lie with them, but without their advice and co-operation the right atmosphere and the appropriate conditions for the most fruitful research are unlikely easily to be worked out. However firmly the universities hold to their own highest traditions of disinterested inquiry, however far they succeed in establishing conditions where research can be carried out at leisure and free from financial worry or embarrassment, however much there and in industry the spirit of service to the community adds an incentive to that of the quest for truth, the co-operation of professional associations will still be required. It must be admitted that in the past such associations have been slow to recognize their opportunities or their wider responsibilities.

# MEDICAL EDUCATION IN GREAT BRITAIN

THE report of the Inter-Departmental Committee on Medical Schools, of which Sir William Goodenough is chairman, is summarized on p. 322 of this issue. The report itself must be read if the Committee's recommendations are to be fully understood. Some of them involve considerable changes in outlook and teaching in both the schools and universities of Britain; others profoundly concern the general public; yet others will hearten the reader and lead his thought beyond the technical details of medical education. For medical work must always be closely bound up with the structure and work of society, and the medical practitioner has to play an important part in social evolution. Any serious consideration of his training must therefore be just what this report is—a sociological as well as a medical document. Several of the reforms which it proposes are similar to, if not identical with, the reforms recently suggested by the Planning Committee of the Royal College of Physicians (which were summarized in the *Lancet*, 607; May 6, 1944, and the *British Medical Journal*, 668; May 13, 1944), so that the views of these two committees can be considered together. In both, the inevitable interaction between scientific method and the older ideal of the art of medicine is evident, and both reports seek to preserve the best elements of the two methods of approach to the patient. Both emphasize the future need to ensure the maintenance of health rather than to await the onset of disease.

The recommendations of the Goodenough Report have the support of "the vast majority of those who are responsible for and engaged in medical education and research in all parts of Great Britain". They must therefore carry great weight. This report points out that, while some of its recommendations could be introduced during this War, others need time to mature. Even if this were not true, doctors cannot be quickly produced, and both the reports under consideration should be read by those who are confronted with the very urgent need for large numbers of doctors in India (see *Nature*, 658; May 27), and elsewhere. In the U.S.S.R., where the need has been, and still is, urgent, a system based on the idea of industrial 'shifts' has been utilized. It is good to know that the Goodenough Committee, which is able to plan for a country in which the need is less insistent, prefers quality to rapid production. Wide publicity should be given to its firm statement that medical schools should regard themselves as under a definite obligation to do all in their power to meet the need for more doctors, but that they should not take in more students than they can train properly. This Committee urges that, in order to shorten the time lag between the initiation of the reforms which it proposes and the production of their results, action should be taken as soon as possible to create postgraduate courses for practitioners, to build up an adequate supply of teachers, and to assist medical schools by means of financial grants, priority of building materials and labour, and so on, and by provision of adequate staffs, accommodation and equipment. But the Committee also urges that all its recommendations should be initiated as soon as possible, because the success of many schemes of non-medical post-war development will depend upon an adequate supply of doctors who have the right training and outlook. Greatly increased financial support from public funds will be required if we are to secure a sound foundation for national health. The total capital expenditure that should be incurred may amount, within ten years, to ten million pounds at pre-war costs, and recurrent grants will have to be increased until they total, after ten years, three or four million pounds a year at pre-war values. These increases in recurrent grants would thus represent, after ten years, only 2 per cent of the estimated cost, in the first year, of the national health service. It will be agreed that this is a "reasonable price for the community to pay for a service which is vital to the promotion of national health".

As the Goodenough Report says, "Properly planned and carefully conducted medical education is *the* essential foundation of a comprehensive health service". The Committee thinks it advisable to stress this point, because current discussions of a health service show signs of premature concentration on the detailed structure of such a service and neglect of its essential foundation, and because problems of medical education and research are not the exclusive concern of the medical schools and the medical profession. The general public should maintain a lively and understanding interest in them. The doctor of the future will, the report suggests, become the adviser on the health of both the individual and the community, and will have the responsibility of ensuring one of the principal aims to which national policy is being directed, namely, the achievement by everyone of the highest possible standard of physical and mental health. This is but a modern statement of that spirit of service which has been at all times the distinguishing mark of the medical man.

While the nation can, the Goodenough Committee thinks, rightly be proud of British medical practice and education as it is, the doctor has not been adequately trained in the past to shoulder his new responsibilities for national health. He has studied disease itself more than the promotion of health—and disease chiefly as it is seen in individuals. He has been taught, as the *British Medical Journal* (648; November 20, 1943) pointed out, too much about how people die and too little about how they live. One of the basic proposals of the Goodenough Committee is that emphasis must be placed throughout the whole of undergraduate and postgraduate medical training on a sound knowledge of how to produce and maintain a healthy nation. This is made clear in the section of the report devoted to social medicine. A new orientation of medical education is required to give effect to this general idea. It involves a big expansion of the social work of hospitals and radical changes in the outlook and methods of most of the teachers. The developments discussed in this

section on social medicine will interest the layman profoundly.

The layman will be no less interested in the chapters of the report devoted to child health, maternity and psychiatry. Better provision for the welfare of children and their mothers will have to extend beyond the sphere of medicine; but doctors will have to play a leading part in them. In general, the teaching about children and their mothers has not been adequate, and proposals are made to remedy this deficiency. If, moreover, the doctor is to grasp modern conceptions of disease or to treat some illnesses properly, he must have better instruction in the normal and abnormal working of the human mind. Every medical school ought therefore to have a department of psychiatry, the work of which should be related to that of other departments. The supply of teachers for these departments also is inadequate, and their training is an urgent need.

In their discussions of all these matters the two reports under consideration agree in main principles. Both also express similar views on the necessity of teaching principle and method rather than fact, especially during the early training of the medical student, on the requirement that at least a year should be spent in a resident hospital post, on the need for drastic reorganization of the medical curriculum with a concomitant reform of the examinations held, on revision of methods of selecting medical students and on the need for adequate training and remuneration of the teachers of medicine and for the betterment of the position of the clinical teacher.

The Committee of the Royal College of Physicians proposes that all university fees should be abolished—a proposal which is not so revolutionary as it sounds when we remember that, as the *British Medical Journal* has reminded us (665, May 13), the present fees paid cover only about one third of the cost of the education given. The Goodenough Committee does not go so far as this. It is not, indeed, within its terms of reference to consider university fees in general. But it makes proposals for the financial maintenance of the medical student throughout his whole training and others for the supervision of his health, housing and recreations which go much further than mere remission of fees. If they are adopted, no parent, however meagre his means, need hesitate to launch his son or daughter upon the varied adventures in public and private service which medicine makes possible; nor need he worry about his child's health or future opportunities. The daughter, moreover, would no longer have to run the risk of exclusion by the medical schools. Co-education of men and women would be universal and Exchequer grants could be withheld if reasonable numbers of women were not admitted.

This question of the selection of the prospective medical student would seem, indeed, to be the keystone of the recommendations of both these committees. For both insist that the right kind of student must be obtained at the very beginning and that all classes of society must be enabled to provide candidates for medicine. Both committees further insist that the medical student's character and personality must be adequately considered when he is being selected. Both dislike selection by examination alone, because this favours undesirable specialization at school and thus may prejudice that broad school education which the doctor especially requires.

Whatever the decision may be about the necessity or otherwise of a selecting examination, it is clear that the task of interviewing every candidate for admission to our medical schools would be a formidable one. It would not be easy to make sure that the interviewers created and maintained in the future a uniform standard of selection all over the country. They would have to interview, the *British Medical Journal* (655; May 13) states, some 2,500–5,000 prospective students every year; and, if the number of doctors is going to increase considerably, as the Goodenough Committee suggests that it will, this task of interviewing would increase in proportion. Nor will everyone feel disposed to give the school record too large a share in the selection of our future medical men. The real characters and abilities of boys and girls are not always discernible at school; they can also be easily misunderstood by some interviewers who may have nothing to guide them but what they can learn at a single interview, together with a school record of doubtful value and perhaps the opinions of a school teacher who, however able he may be, must often, especially in large schools, imperfectly understand some of his pupils. Both school teacher and interviewer might easily fail to discern abilities which, even if they did not fit a pupil to become a good medical practitioner, might help him to do good work in other fields of medicine.

The humble potential patient in all of us may be even more doubtful of tests of intelligence or aptitude which might, it is suggested, help in the selection. It will not be surprising, indeed, if many readers of these reports reject all the arguments which would seek to reduce the importance and efficiency of that popular scapegoat, the examiner. They may not wish to adopt the desperate remedy once proposed by no less an authority on the human mind than William McDougall, namely, examinations for the selection of examiners; but they may suggest that examinations can be altered and that it should not be an insuperable task so to modify the university entrance examination—which is the standard of entry to medicine required by the Goodenough Report—that it would at any rate help to select the qualities required in the medical student. It might even turn out that the main faults of the examination system lie not in the system itself, but in the type of questions asked and especially in the practice of allocating marks by number. If the selecting examination included an oral examination, which should, so many experienced examiners think, be a feature of all examinations, because it gives the candidate a golden opportunity to reveal just those qualities which cannot be expressed on paper or in a practical test, this could be made the occasion of the interview desired by these two reports.

Taking it by and large, the layman who is to be treated when he is ill by the future doctor may prefer that the character and personality of the medical

student should not be accorded too high a value when he is being selected at the outset of his career by individuals who may never, even if they happen to be specially qualified psychologists, assess them correctly. In any event, these qualities will develop during a course of training which should, if it is properly designed, eliminate the misfits and direct them to more suitable work. The Goodenough Committee, in fact, specifically proposes that there should be means of eliminating such misfits as early as possible in their undergraduate careers. Selection can, in other words, be imposed too early, and the value of the natural selection of the medical school and the hospital can be under-estimated. This is especially true of the medical student, who cannot possibly know, until he begins to handle patients, whether he either wishes to be, or is fitted to become, a practising doctor. It would therefore seem to be wiser to emphasize selection at a later stage of his career, when he has tasted clinical work. Little would be lost by this if the Goodenough Committee's excellent provisions for the direction of each student into the sphere of work for which he proves to be best fitted are adopted. This would amount, in effect, to the selection by each student of his own career. It seems a pity that all university students cannot be given, by means, for example, of a first year during which they could taste, under the guidance of a tutor, every field of university work, a similar chance to select, under supervision, the work which offers them the best chances of combining in their lives a natural inspiration and interest and service of practical value to themselves and to the community. For the value to medicine of the non-medical worker is well recognized. The Goodenough Committee would, in fact, make special provision for the assistance of workers in other fields who may wish to switch over to the study and practice of medicine. There is no better background, it says, to a medical training than a university course in some other faculty, and it believes that the medical profession would benefit if more graduates in classics, history, languages or pure science entered it.

Although many readers of these two reports may prefer the proposals of the Goodenough Report for the selection of the medical student to those of the Committee of the Royal College of Physicians, all will agree with both committees that the masses of detail which now clutter up the medical curriculum should be resolutely pruned away. The emphasis, both Committees think, should be, during the early training in any event, on the teaching of principle and method. It will not be easy to select for removal the detail which the medical student will not require unless he should be able to show, at a later stage, that he is fitted to become, say, an anatomist, a surgeon, a pharmacologist or to enter some other field of work which requ res the acquisition of detailed knowledge. The Goodenough Committee rather emphasizes the difficulty of this task; but it does not shirk it. Such pruning could, its report suggests, reduce the duration of the medical training to four and a half years, and the report indicates the advantageous use of the time thus saved. This Committee further recommends that the curriculum should be constantly reviewed in the future by each medical school rather than by any body specifically appointed for this purpose. It will be necessary, however, not to exalt the teaching of principle and method so high that the value of factual knowledge is depreciated too much. The Goodenough Committee emphasizes the teaching of observation and deduction of the meaning of facts observed and also the proper statement in words of these facts and deductions. But, although the student who crams facts can pass many examinations, whether they be medical or not, the training of the memory must not be neglected. Much of the practising doctor's efficiency depends upon a memory for detail, because it is done under conditions and in places which preclude consultation with others or reference to books. On the other hand, many of the existing text-books in common use should, it is widely agreed, be either scrapped altogether or entirely rewritten. The Goodenough Committee's plans would markedly reduce the doctor's need for books and works of reference: in place of them it would substitute constant living and personal contacts with specialists and others whose job it would be to keep the student and the practising doctor up to date and in touch with the latest methods and knowledge. There would be, for example, abundant and wisely planned postgraduate courses for practitioners and for any others who required them. The reorganization of the medical teaching centres and their better distribution about Great Britain would largely remove the geographical difficulties of any individual doctor who wished to keep his knowledge and practice up to date.

The training given to the student should provide him with an abiding eagerness to excel in current practice and to forge new tools for the service of his fellows. The Committee of the Royal College of Physicians emphasizes the convergence in medical education of the vocational education of the medical school and hospital and the academic training of the university. Sir Thomas Lewis (*Lancet*, 619; May 13, 1944; and 649, May 20, 1944) has discussed the same theme in some detail. The Goodenough Committee's proposal that every medical school should be an integral part of a university would give the medical student both these kinds of training. Clearly he must have both, even at the cost of the proposed disappearance of the Scottish extra-mural medical schools which have given much good training in the past.

The early clinical training should, the Committee of the Royal College of Physicians believes, be an organized system of teaching correlated with the pre-clinical studies and with pathology, and it proposes an undergraduate clinical course, lasting three years, during which the teaching would be directed to principles and methods and the development of judgment rather than to the acquisition of factual knowledge. The Goodenough Committee formulates in detail a similar scheme, which is coupled with a scheme of pre-clinical teaching. The report urges the immediate initiation of this scheme. The whole scheme could not be adopted at once, because it

involves far-reaching changes, some of which require some years for their completion. They are outlined on p. 322 of this issue. Those which concern the appointment of more whole-time clinical teachers and the betterment of their salaries and conditions of work need not be long delayed and are urgently required. It should not be very difficult, especially in these times of rapid large-scale reorganization, to establish quickly one or more of the medical teaching centres described by the Goodenough Committee; or to put into operation this Committee's plan for a Postgraduate Teaching Centre in Hammersmith; or to establish the experimental undergraduate medical school recommended for the University of Oxford. If these were started any faults in the schemes laid down for them would be the more quickly detected and remedied, and also more readily integrated with the national health service, which will itself require amendment as experience of its practice grows. Universal co-education of men and women in medicine, which the Goodenough Committee places in the forefront of its programme, should certainly be introduced immediately. It has, this Committee tells us, been the normal and successful practice for many years in all the medical schools outside London. It is time to end for good this injustice to our women. It would be of little use, however, to introduce this urgent reform unless steps were also taken to implement the Goodenough Report's further recommendations that all hospital appointments for qualified practitioners should be filled by open competition, and that the sex of the applicant should not be a bar to these appointments.

The mention of the qualified practitioner brings us to the important recommendations made by both the reports under consideration with regard to medical qualification. The Committee of the Royal College of Physicians would institute a final medical examination consisting of two parts. The first part would examine the candidate at the end of the three years clinical course which this Committee recommends, and this would be designed to test the candidate's knowledge of principles and methods rather than his knowledge of facts. On its results the candidate would receive his medical degree; but this would license him to practise medicine only in a hospital under supervision. He would still have to show that he is fitted to practise independently. To demonstrate this he would have to spend a compulsory year during which he would hold paid resident hospital appointments in general surgery, general medicine, obstetrics and gynæcology, pediatrics and child health and in special studies. At the end of this year of hospital work the second part of the final examination would be taken. If the results of this showed that the candidate had sufficient practical and vocational ability, he would get his licence to practise independently. His further career would presumably be bound up with the national health scheme.

The Goodenough Report proposes a scheme conceived on the same general lines, but with only one examination; and many will think that it is the better scheme of the two. There has been, this report says, enthusiastic support for its recommendation that every medical student, after he has qualified but *before* he is admitted to the Medical Register and allowed to practi e independently, shall be required to serve as a junior 'house' officer for a year at one or more approved hospitals. Before this War about half the students admitted to the Register did this, and during the War, regulations and conditions have raised this figure to more than 90 per cent. These 'house' appointments should be confined, the Goodenough Committee thinks, to departments of general medicine and surgery and each appointment should last at least six months. While they last the student should be enabled to obtain experience in special departments, but 'house' appointments in these special departments and in departments of obstetrics and gynæcology should be held *after* he has been admitted to the Medical Register. The Goodenough Committee does not propose a second examination at the end of this compulsory period of hospital appointments. It would be sufficient if the student submitted, when he applied for admission to the Medical Register, certificates to the effect that he had held the required appointments to the satisfaction of the authorities concerned.

The uninstructed layman, who may be concerned very closely by these proposals, will no doubt heartily welcome them. They should, if they are combined with the Goodenough Committee's other recommendations, ensure for the public, in both health and sickness, the care of doctors who are doing their job because they like that kind of work and because they wish to serve their fellow men and women; and the work would be done by doctors of both sexes who would be as up to date as any planning can help to make them. If the public should get this kind of service—and it is to be hoped that the doctors themselves will be allowed to plan it, if only for the reason that they began to feel their way towards it long before any Government realized the necessity for any organized system of national health—the public itself has an obligation on its side. It must help the doctors. It must help to keep them as free as any other citizen to organize and do what they consider to be in the best interests of their patients. It must trust them when they say that their main purpose is to serve, as the best of them have served since the days of Hippocrates, their fellow men and women and to keep them in health, rather than to wait until they have to be treated for lack of health. We must all help also by allowing ourselves to be used, either as models of health or for the instruction of medical students in the signs and symptoms of disease. We must realize that we are members of a society inseparable from modern medicine and must therefore think as well as we can about the aspirations and difficulties of our doctors. We must think, too, of the betterment of the lot of women and children, which the recommendations of the two reports under consideration would inevitably bring about. These two reports, in fact, express, in a particular field, a major trend of modern thought which is exerting its practical effects all over the world.

# BOOKS: THE WAREHOUSE OF KNOWLEDGE

THE technical agencies in education and in the dissemination of knowledge are growing in kind and variety. In our basic seminaries—the schools—we have the teacher in the class and lecture rooms, the experimental laboratory, the workshop and garden, the cinema, the radio, and so forth. These are immediatly effective; but very seldom may the pupil refer back to them when and where he will.

In this respect the text-book differs from all these. Although the film, for example, can describe and illustrate, especially scientific phenomena, in such a way that no text-book could emulate, nothing but the book can claim the quality of permanence or give the enthusiastic pupil that pride of possession which is an essential need to the immediate aim of acquisition of knowledge and the ultimate aim of a good education. The pupil can refer back time and again to his books, he can read and re-read until he has digested all those books have to offer.

Furthermore, books and journals are practically the only means whereby an individual person is able to keep a record of the progress of knowledge. *Nature* itself, for example, is not only a forum for scientific discussion and a newspaper for men of science, but it also aims at building up a printed and therefore a permanent record of scientific progress and discovery, so that an issue of *Nature* of thirty years ago is in certain respects as valuable as this week's issue. This cannot be said of any other of the above-mentioned agents of education, in so far as any one individual person is concerned, since so few can hope to make a library of films.

Books and journals, therefore, must for a very long time continue to hold a unique position both in general education and technical training.

Unfortunately, unless help is quickly forthcoming, we shall soon find that the supply of books for all purposes, including general education, scientific advancement and research, medicine and so on, will be totally inadequate to meet even essential requirements.

A brief review of the present position carries this conviction.

The last year of peace was bad. We were living in suspense, and even education authorities were making do with books in hand rather than make their normal annual purchases. Publishers themselves restricted their activities because of the threat of war.

Thus, book production for 1938–39 was small, but the paper now allocated to publishers for books amounts to 40 per cent of their 1938–39 consumption —and a recent ruling of the Paper Control has made it impossible for publishers even to obtain their full quota.

Certain agreed restrictions such as thin paper, small page margins and small type have enabled such books as the ordinary novel to be produced on very much less paper per book, but other types, such as school books, were already produced on a strictly economical basis. Accordingly, the numbers of school and university texts, etc., that can be produced has probably been cut by something like 50 per cent throughout the period of the War.

In 1939 publishers carried good stocks of books and paper; but this reserve of paper has now been used, and the stock of books is rapidly decreasing.

Figures collected by the Publishers' Association from representative publishers show the following result:

| | Books |
|---|---|
| Stocks at end of 1942 .. .. | 33,136,254 |
| Printed during 1943 .. .. | 12,184,277 |
| | 45,320,531 |
| Sales during 1943 .. .. .. | 18,146,471 |
| Stock at end of 1943 .. .. | 27,174,060 |

With pre-war stocks of paper gone, the production for 1944 can reasonably be put at 10,000,000 books only. The sales for the year, though really governed by supplies, could not be put at less than 25 per cent up on 1943. This would give us the following position:

| | Books |
|---|---|
| Stock at end of 1943 .. .. | 27,174,060 |
| Estimated printed during 1944, say | 10,000,000 |
| | 37,174,060 |
| Estimated sales during 1944, say | 22,674,060 |
| Estimated stock at end of 1944, say | 14,500,000 |

Thus one more year will put the publishing of books, etc., on a real hand-to-mouth basis.

It must also be remembered that much of the stock shown in the above figures are still pre-war books in slow but constant demand—many of them are important books of their type, but they are not books that are in urgent and immediate demand. Accordingly, it is quite likely that some 10,000,000 of the stocks shown above should be deleted altogether from consideration of books available for immediate urgent necessity.

But the consumption tends to increase not merely rapidly but alarmingly. Schools that have made do for several years now wish to return to efficiency again. An enormous scheme is on foot for Army post-war education. And so it goes on. For home and export, books of all sorts are vociferously demanded.

What is the publisher to do? The demand is for all types of books—one type cannot be sacrificed to help another. Orders pour in.

The publisher is practically driven to printing small editions. This is a most uneconomic proceeding and entails increased prices to the public. An even worse effect is the additional work per book thrown on to printers and binders. Making ready, as it is called, is a very lengthy process and these short runs materially reduce both binders' and printers' output.

So we arrive at the state when even an increase of paper will not immediately ease the situation. It will take time to get back to longer runs, and it is vitally urgent that this return to economic methods of production be initiated forthwith.

Incidentally, publishers may be almost entirely

absolved of pressing for financial gain. Excess Profits Tax sees to that, and larger sales will only swell the Government's receipts—not the publisher's.

Printers and binders have, of course, been denuded of labour. Notwithstanding early official statements that books were necessary to the prosecution of the War, the book trade has been largely unprotected, and surely the time has now come to give the trade a chance to turn out the millions of books that are admittedly essentially required.

As mentioned above, demands are being received for books for Army education. Extra paper is promised for these, but printers and binders are not able to deal with additional work. As pointed out, a general increase in paper supplies would tend to ease the situation, but it is not possible to impose further demands on printers and binders whilst they are handling the present multitude of short runs.

However, the offer proves additional paper is available, as indeed do long-established cases of books produced of a popular technical nature for which paper has been made available by one or other of the Services. We do not know who has the authority to say which books are sufficiently valuable to the Services to merit Government paper, but we question his decision in many cases.

However, the Government has plenty of paper at its disposal, as indeed H.M. Stationery Office must now rank high as regards the quantity of its publications. Is this continuous stream of Government-backed but apparently unofficial pamphlets and booklets of greater value than the type of books which have been in demand for many years? Who has decided that this is the best use for paper in war-time?

The current consumption figures for paper as follows are of considerable interest:

| | Tons |
|---|---|
| Newspapers .. .. .. .. | 250,000 |
| H.M. Stationery Office .. .. | 100,000 |
| Periodicals .. .. .. (nearly) | 50,000 |
| War Office (included in H.M.S.O. quota) .. .. .. .. | 25,000 |
| Books (including the extra 2½%) .. | 22,000 |
| American Book Publishers' quota for 1943 was .. .. .. | 128,000 |

Presumably much of the War Department paper went on training booklets and the like. Surely training has now decreased to some extent, so that the publishers could have some or all of the now redundant paper. What about the Civil Defence Services? Surely these are organized now and could reduce their requirements for paper. And so with other Government Departments. At the same time, this reduction of H.M. Stationery Office paper consumption would reduce their compulsory orders to printers and binders. This would further help to square out the vicious circle now fettering the book trade.

For four years, educationists and men of science have valiantly shouldered the heavy burdens imposed by the short supply of essential literature in the form of text-books and technical journals. But surely science can claim war-time priority; furthermore, war or no war, progress in education must not be allowed to stop altogether, though it must, of course, *pro tem.* reduce its pace.

At present, of the 420,000 tons of paper in the country available for printing, only little more than 5 per cent is allowed for books—and this comprises books of all kinds, including those which with no stretch of the imagination can claim to have literary or educational merit. This position can and should be adjusted if educationists and men of science are to be encouraged to give of their best—and their roles at the present time, and even in the more difficult years of peace-making and reconstruction to follow, are of the highest importance. Readjustment can be made fairly simply by modifying the percentage of quotas.

# INDUSTRIAL TOXICOLOGY

**Industrial Toxicology**

Being the Croonian Lectures for 1942 of the Royal College of Physicians of London. By Dr. Donald Hunter. Pp. 80. (Oxford: Clarendon Press; London: Oxford University Press, 1944.) 10*s*. net.

ANY review of the present field of industrial toxicology necessarily suffers from the fact that it is more or less an 'interim' report, issued during a period when comparatively little has been added to the pre-war knowledge of existing toxic substances, and before the expected development of many new agents which may or may not prove injurious to workers exposed to them.

It is well that existing knowledge should be brought up to date, both from the biological as well as the purely chemical and physical aspect.

The latter is specially emphasized in Dr. Donald Hunter's review of a large number of toxic substances encountered in industry. Immunity from danger in handling many substances essential to industry both in war and peace depends to a large extent on accurate recognition of the chemical and physical properties of those already known to be toxic. Such knowledge can be usefully applied in forecasting the probable potential toxicity of new substances the harmful effects of which have not yet been emphasized by the results of bitter practical experience.

In Dr. Hunter's review, the relationship of chemical constitution and physical properties to biological activity is shown by many examples in the various groups of metals, aromatic compounds and chlorinated hydrocarbons. A typical difference in effect of the same element in different chemical combinations is the contrast between the manifestations of poisoning by inorganic lead, where true lead encephalopathy is now rarely seen, and the cerebral disturbance, sometimes terminating in violent mania, which is the outstanding phenomenon in poisoning by the organic compound, tetra-ethyl lead, and is unaccompanied by the classical symptoms of lead colic, palsy or punctate basophilia. The picture of severe chronic benzene poisoning, with the most frequent effect of aplasia of the bone-marrow, is also quite distinct from the specific capacity of the nitro- and amino-derivatives of benzene to convert hæmoglobin into methæmoglobin, and the special tendency of the amino-derivatives to attack the bladder, causing papillomata which may become malignant.

The large group of chlorinated hydrocarbons used in the rapidly growing cellulose lacquer and plastics industry show very clearly this variation in toxic effect according to chemical constitution. Halogenation appears to be closely related to liver damage, and increase in the chlorine molecule, though compensated to some extent by decrease in volatility, generally increases the toxic effect. Thus tetrachlorethane, no longer used as an aeroplane dope on account of its high toxicity, is about four times as toxic as carbon tetrachloride, while trichlorethylene is much less likely to attack the liver than either.

Recent investigations on the biological effects of toxic substances are described less fully. Only a very brief reference is made to an investigation on the mode of action of carbon tetrachloride when exposure is relatively mild and of long duration, as opposed to the better-known acute intoxication arising in connexion with its use as a fire extinguisher. Much light was thrown by this investigation on the true origin of the gastro-intestinal symptoms frequently observed in workers using tetrachloride as an industrial solvent.

A slightly more detailed account is given of an examination of the effects of trinitrotoluene, the experimental subjects being a number of students who volunteered to fill shells during their vacation. Very valuable information was thus gained as to the reaction of living tissue to T.N.T. without the accompaniment of severe or irreparable injury.

Of the newest group of industrial agents, the glycols, comparatively few have been fully investigated, but some, including ethylene chlorhydrin and diethylene dioxide (dioxan), have already given proof of their potency for causing damage. The cases of fatal dioxan poisoning which occurred in 1934 should act as a special warning against the assumption that substances which have never actually proved toxic can be regarded as harmless. Dioxan had not only been shown to be comparatively innocuous to animals, but the five men who died from hæmorrhagic nephritis had been exposed to it for nearly sixteen months without apparent ill-effect. It was only when exposure to the vapour was intensified by the speeding up of the machine and by the necessity for the men to put their heads into the vat containing dioxan that severe injury to the kidneys occurred.

The new aliphatic chemical industry, which has made great strides since 1925, may be expected to expand still further in the post-war years, and many substances of the group to which dioxan belongs may then reveal their true biological effects. At present their chemical and physical properties are better known than their potential toxic action, and it is to be hoped that this knowledge will be applied on the basis described in this review.

ETHEL BROWNING.

## A SURVEY OF STATISTICS

Statistics

By L. H. C. Tippett. (Home University Library of Modern Knowledge, No. 156.) Pp. v+184. (London, New York and Toronto: Oxford University Press, 1943.) 3s. net.

FEW sciences are more difficult to present in a concise and readable manner than statistics, which is regarded as a symbol of all that is dull and devoid of human interest. "What you've got," says Idaho Green in one of O. Henry's stories, "is statistics, the lowest grade of information that exists." To give the general reader an idea of the fascination of astronomy, biology and even mathematics is relatively easy; but this is the first attempt I have seen to perform that very useful function for statistics.

Mr. Tippett is to be congratulated on having made a success of his undertaking; and indeed, it is hard to think of anyone better qualified to attempt it. His familiarity with both the theoretical and practical sides of his subject, coupled with his interest and experience in the teaching of statistics, have contributed to an excellent Pisgah-view of a complex, dry and extensive domain. He is never at a loss for a practical illustration in point, but does not lose the thread of the main argument as is so easily done in a discussion of statistical examples. Within the limitations imposed by its length—about 50,000 words with a few tables and no algebraic symbols—he appears to me to have done just what is wanted of volumes in the Home University Library, to have given a general review of his subject for those who want to know what it is about and sufficient enticement to those who are likely to want to extend their knowledge further.

Mr. Tippett begins with four chapters on raw statistical material and its arrangement, presentation and summarization. The points he makes about pitfalls in the interpretation of numerical data, elementary as they seem, are so important to the average citizen that one wonders whether some part of this branch of the subject should not be taught in schools. I do not quite share his view about the readiness with which unpublished official information is put at the disposal of the private research worker. There seems to be a school of thought which holds that any material collected at the public expense by public servants for the public benefit should on no account be made public. But perhaps this feeling is coloured by war-time experience. It is to be hoped that after the War the State will realize that as much as possible of the information it collects should be published, or at least put at the disposal of 'unofficial' research workers.

The next group of chapters deals with sampling, probability and statistical laws. A further chapter on statistical reasoning is exceptionally good, and it is a real relief to see someone having a tilt at the prevailing methods of presenting numerical information about the progress of the War. One gets very tired of statements that our production of something or other is ten times what it was a year ago (which means that a year ago it was only one tenth of what it is now) or that the total tonnage of bombs dropped on Germany in some selected period is four times the weight dropped on England in some other period. Considerations of secrecy are admittedly paramount; but all the same censorship covers a multitude of statistical sins.

The concluding chapters deal with statistics in affairs and statistics and the other sciences. Mr. Tippett has only the space to deal with these topics in broad outline, but he contrives to give a very fair impression of the enormously wide interests of the statistician at the present day.

One criticism may be advanced. In the list of books for further reading at the end Mr. Tippett, with misplaced modesty, omits a reference to his own book on "The Methods of Statistics", a useful work which has done a good deal to spread the newer methods among scientific workers.

M. G. KENDALL.

# MEDICAL SCHOOLS IN GREAT BRITAIN

## THE GOODENOUGH REPORT

ON pp. 315–318 some of the main recommendations of the Report of the Inter-Departmental Committee on Medical Schools* are discussed. The length of the report and the detailed survey which it presents of existing medical organizations and the radical reforms which it recommends make it impossible to do more at present than to give here a brief summary of its main contents.

While the unity of medicine and the individual freedom enjoyed by medical schools in academic matters must be preserved, medical education must in the future develop the mind and character of the medical student in such a way that he can acquire a liberal university education, a scientific foundation for his work, an adequate knowledge of disease, a proper outlook on the promotion of mental and bodily health, a sympathetic understanding of people and their environment and sound judgment and ability to observe accurately, reason logically and assess the value of new knowledge. The emphasis in training should be on principles and methods rather than on the learning of facts, and there should be a bias towards the needs of the future practitioner. The report bears in mind the Government's plans for the future health of the nation.

The unit of organization for the future national system of undergraduate medical training should be a medical teaching centre, consisting of a university medical school and a group of teaching hospitals, comprising parent and associated hospitals situated as near as possible to the medical school, together with those clinics of the health service of the district which can be used for teaching. All these would function as a unit, but each constituent body in each teaching centre would retain full authority in its own field of responsibility.

Reviewing the existing medical schools in relation to this unit of organization, the report lays down the principle that every medical school should be an integral part of a university. Of the thirty existing medical schools in Great Britain all but four are university medical schools. The report proposes that the three extra-mural medical schools in Scotland, namely, the School of Medicine of the Royal Colleges of Medicine and Surgery, Edinburgh, the Anderson College of Medicine, Glasgow, and St. Mungo's College, Glasgow, should cease to train students. The report gives a valuable history of the development of these Colleges and also of their relationship with medical education, and pays a tribute to the excellent work which they have done in the past; but it is considered that they are not adequate to the modern needs of medicine. The work of these Colleges and the possibility that the proposals of this report may eventually result in the disappearance also of the 'Conjoint' diploma granted by the Royal Colleges of Physicians and Surgeons of London are discussed by the *British Medical Journal* (154; July 29, 1944). The Goodenough report also proposes that the West London Hospital Medical School should cease to train students within the next four or five years. The Committee recognizes its excellent work, but its proposed disappearance is related to the report's other recommendations relating to the University of London. Medical education in London, indeed, constitutes a special problem the various aspects of which the report considers at considerable length.

No changes are recommended in the administration of the university medical schools in Scotland, Wales and the English provinces, except that it is recommended that the governing bodies of the hospitals should be represented in the government of the medical schools wherever this is not at present the practice. The Committee also thinks that, although participation by the dean of a medical school in academic and teaching work is valuable, the dean of the future will probably not be able to continue this kind of work and that he will have to be a whole-time salaried official. But in London administrative changes will be necessary. It is recommended that all London University undergraduate medical schools should become separate legal entities, that the University of London and its medical schools should be more closely associated and that the University should be represented on the governing bodies of its medical schools. Both the University and its medical schools will need to make contributions to this development. Further, the geographical distribution of the London medical schools was, the Committee thinks, unsatisfactory even before the War. This subject is discussed in relation to the tendency of the population of London to move from the inner to the outer areas of London, to the consequent likelihood that hospitals in the centre of London will not get so many patients and to the need to provide individual medical schools with increased teaching facilities.

The complexity of this problem can only be realized by reading the discussion of it in the report. The Committee's conclusion is that, as soon as possible, Charing Cross Hospital should move to a site in Middlesex and St. George's Hospital to a site, say, in South London where hospital accommodation is urgently needed; and that, when this is done, the medical school of each of these hospitals should expand and provide both pre-clinical and clinical training. These moves would leave a distribution of medical schools and their parent hospitals which would be reasonably satisfactory, except in the area in which University College Hospital, Middlesex Hospital and the Royal Free Hospital are grouped, together with nineteen other hospitals, within a radius of one mile. Six of these hospitals are, moreover, special hospitals in which postgraduate education should be developed. It seems extremely doubtful, the report says, that this area will, under a co-ordinated hospital system, be able, in a few years' time, to provide adequate clinical teaching for three medical schools of the size that is contemplated by the report. It is therefore suggested that the London School of Medicine for Women and the Royal Free Hospital should consider a removal. A site in the northern suburbs of London, such as Highbury, is suggested.

The Committee's views on the selection of students are also progressive and in line with modern trends of educational thought. They are discussed elsewhere in this issue. Financial assistance to students is considered in detail. Scottish faculties of medicine draw students from all classes of the community, but England and Wales do not draw them from so wide a field, largely because parents do not understand how much assistance can be obtained and because

* Report of the Inter-Departmental Committee on Medical Schools. (Chairman: Sir William Goodenough.) Pp. 306. (London: H.M. Stationery Office, 1944.) 4s. 6d.

secondary school students are not sufficiently encouraged to take up medicine. The report states that grants to medical students should cover the whole period of training and should cover the cost of maintenance, which is the greater part of the cost. The machinery for awarding public funds for this purpose should be simplified and private organizations and charitable trusts should keep in touch with those who administer public funds. Medical schools should have more adequate funds for the assistance of students.

The wide range of interests in medicine and the fact that lack of money need not debar anyone from taking it up should be brought home to all parents. It is the primary obligation of British medical schools to train students born in Britain, but suitably qualified students from abroad, and especially those from the Commonwealth and the Empire, should be welcomed. Every university should have a students' health service with a medical man in attendance. Medical examination of students at the beginning of their training and at intervals thereafter, the provision by the universities and medical schools of nourishing meals at reasonable prices and of facilities for exercise, games and recreation are recommended, and the value, especially for medical students, of residential college life is stressed, because the relations of people to one another will play such a large part in their future work. Many students will have to live in lodgings until accommodation of this kind can be provided, so that supervision of lodgings and the health of students living in them should be a responsibility of those who are training them.

Dealing with the larger question of the number and distribution of British medical schools, the report points out that it is expected that the number of civilian practitioners will continue to grow for some years to come. To provide for this it is better to expand the existing medical schools rather than to create any new ones. Plans for these expansions are given.

The Universities of Oxford and Cambridge are considered separately. At Oxford the medical school was, before 1937, mainly a pre-clinical one, but during the War, a complete undergraduate medical training has been given. The University does not wish to continue this in its present form, but wishes to retain it in a specially modified form, designed to develop teachers, investigators and consultants, rather than general practitioners. There would be only a small number of students and these would be carefully selected and would be instructed individually, with special emphasis on the scientific approach to medicine. Only about fifty students would be admitted to the pre-clinical course and about 20–25 a year to the clinical course. Students who had taken their pre-clinical courses elsewhere would be admitted and exchanges with other universities in Britain and overseas would be encouraged. The Committee thinks that there is a fair chance of the development in Oxford of the kind of medical teaching centre which its report proposes, and it thinks that Oxford should have the necessary financial aid to continue a small clinical school after the War. It would, the report says, be opportune to give, after the War, an existing undergraduate medical school this kind of opportunity to develop on new lines; it might open up a new era in medical thought and practice. "One radical experiment in the training of medical students promises a most effective means of fostering improvements," which may well influence the character of medical education in the next generation. At Cambridge, the recent discussions there of a scheme to establish a clinical school are reviewed, and the report concludes that such a school should not be established until the local hospital services are raised to a very much higher standard. Active postgraduate clinical departments should first be created. These are most desirable and can be developed piecemeal. A beginning might be made with departments of psychiatry, experimental medicine and radio-therapy.

Dealing with hospitals the report points out that in the past the needs of medical education have not been emphasized sufficiently and teachers of medicine have not had sufficient voice in the management of teaching hospitals. It is suggested that parent teaching hospitals should not become university hospitals, but that the reforms desired should be obtained by giving the governing body of the medical schools sufficient representation on the governing bodies of the parent, and also, though this is not so important, of the associated hospitals. The governing body of the hospitals should be personal to the hospital. The full medical members of the staff should have complete individual responsibility for clinical management of their patients and a medical committee should advise the governing body on medical matters. If a medical superintendent exists, he should not have executive powers over clinical management of patients unless these are delegated to him on the advice of the medical staff. The report considers it important that common advisory machinery should be used by all parts of the medical teaching centre for the selection of the medical staff other than the junior grades, and that grants from public funds should be received through university channels. For details of the clinical instruction to be given in these hospitals or groups of hospitals and of the relations of their staffs to the universities and medical schools the report itself must be consulted. The report insists that every means should be used to bring every hospital into relation with a medical teaching centre and that the spirit of education should permeate the whole service. The medical teaching centre would thus become the centre of a wide zone of influence. If central health service councils are established as a result of the introduction of the national health service scheme, the universities should be given adequate representation on them and should have representatives on the local health services councils in their areas. All these university representatives should have the same status as representatives of other interests.

A section on the staff of pre-clinical departments of medical schools does not propose any fundamental changes, except that it is hoped that selection and appointment of candidates for regius chairs will be transferred by the Crown to the universities concerned. Higher salaries are proposed for teachers of pre-clinical subjects and there should be more senior posts in this category and time to enable junior grades to do research and to read more. Fundamental changes are, however, proposed in the staffing of clinical departments other than those of pathology. At present only a small proportion of the senior clinical staff hold whole-time appointments; the chief occupation of many, if not of most, is private practice and usually they are not paid salaries. Most are selected without reference to the medical schools, and usually there is nobody who is responsible for the organization and direction of clinical teaching

and research. To remedy these faults, the report proposes detailed schemes for the creation of more whole-time and part-time appointments and for the selection of those who will hold them. These would vastly improve both clinical education and the present very unsatisfactory position of the clinical teacher. To this the report adds a long and detailed consideration of the whole curriculum and proposes drastic changes in it.

Some of its proposals for the selection of medical students are discussed on pp. 311–314. Premedical studies are not, the report considers, satisfactory. Training in the physical and biological sciences is, the Committee thinks, best begun at school, and it should be continued at the medical school in close association with training in anatomy and physiology. In the secondary schools this would involve changes in the teaching of science and the provision of suitable laboratories and other accommodation. More teachers would be required by the schools, and improvements in the quality of the teaching, especially in the teaching of biology, are needed. Such changes require time. Considering interim arrangements, the Committee says that it would accept the School Leaving Examination suggested by the Norwood Committee as an exemption from the First Medical Examination, provided that excessive specialization should not be possible, that general science should be taught over most of the school career and not merely during the last two years, that the syllabus should not be a special one for medical students and that general science should be treated non-vocationally with emphasis on principles and methods rather than on the acquisition of facts. Appropriate modifications are suggested for Scotland. Until this plan can be put into practice, medical students should attend a special pre-medical course in general science for one year at the university and should pass an examination in it of approximately the same standard as that of the senior school leaving examination. To emphasize the Committee's desire that the syllabus for this course should, like that proposed for schools, not have a vocational bias, this first medical examination should be called, not the First Medical, but the Pre-medical Examination. The report emphasizes that entry to this examination should be restricted to those whose general education is high enough to allow their entry to the medical course and to those who have prepared for it at a university or university college. The practice of preparing for it during their last two years at school should be discontinued as soon as possible.

The report then discusses what it calls the pre-clinical subjects, namely, anatomy, physiology (including biophysics and biochemistry), elementary normal psychology and pharmacology. The student's training in these largely determines, the Committee thinks, his attitude and methods in the clinical course to follow. Teaching of these pre-clinical subjects should be organized in the closest association with other university departments and with the parent teaching hospital. To bridge the gap between the pre-clinical and clinical courses an overlap of personnel would help, and there should be freer access to patients for the teaching of anatomy and physiology. One medical school is considering teaching anatomy and physiology as two aspects of human biology, and this idea appeals to the Committee, although most medical schools are unlikely to adopt it at present. A committee should organize the pre-clinical studies. An amendment of the Anatomy Acts or new legislation might help to remedy the present shortage of material for the teaching of anatomy. Some instruction in the recording of facts and in the deduction of their meaning should be given. There is urgent need in every medical school for the drastic elimination from the curricula and from the examinations of masses of detailed information. A change of outlook by the teachers should also direct the student's attention to the importance of health and the prevention of disease. More studentships, scholarships and maintenance grants are required to encourage postgraduate students to act as members of research teams.

Certain special arrangements in London occupy a section of the report which recommends that pre-clinical and clinical departments should be near to one another and that, with certain exceptions, every medical school in London should provide for both these parts of the training. Elementary teaching in chemistry, physics and biology for students who have not had this at school should be concentrated at the colleges only, such as University College, King's College, Bedford College and Queen Mary College, which have science and other faculties.

The teaching of pathology receives special consideration. Normally there should be at a teaching centre four departments in this subject, namely, morbid anatomy, bacteriology, chemical pathology and clinical pathology, each with a whole-time professor or other senior officer and adequate staff. A director should be in charge of the whole, and he could be one of the departmental heads; he would have charge of pathological investigations in the parent and associated hospitals. A medical student does not need detailed knowledge of pathology or technical skill; his training in the principles of pathology should be spread over the whole clinical period. There should be day-to-day collaboration between clinicians and pathologists at the bedside, in the out-patients departments and in the laboratories.

In the clinical courses the report seeks, as it does throughout the whole training, to organize correlation between the various subjects taught. An introductory clinical course of not less than four months is proposed to effect a smooth transition from pre-clinical to clinical courses. This course should indicate the relation between the earlier studies of the human body in health and later studies of it in illness, should encourage students to carry to these later studies the scientific thought and criticism which they have learnt earlier and should teach them to observe and interpret the clinical signs of disease. Such a course will make heavy demands on the time of teachers and on clinical facilities. A medical student needs a unified knowledge of medicine and has to acquire it largely from specialists, and this creates problems associated with the growth of specialization. The report proposes that in the training of specialists a sound postgraduate experience should precede specialization. The teaching of students by means of clinical units would be continued, but the report proposes to link these with the academic heads of the five divisions into which it divides the whole training; and it recommends that there should be periodical informal meetings of all the teachers and also that the views of the students should be obtained. For the details of the very interesting discussion of this complex subject, which contains much historical material of great interest, the report itself must be consulted. Among valuable recommendations are the

emphasis on principle and method, the need to give proper attention to the problems with which general practitioners are faced, and to minor ailments and the early signs of disease and to rehabilitation. Some surgical procedures are better taught after graduation.

The report gives a valuable history and discussion of the functions of the General Medical Council. There is need, it considers, of some central source from which medical schools could obtain guidance, and the report proposes to extend the powers of the General Medical Council to enable it to appoint inspectors, who would not be members of the Council, to visit medical teaching centres and report upon the courses of study, staff, accommodation and other matters. Copies of the reports of these inspectors and the comments of the Council and of the institutions concerned should be sent to the University Grants Committee. There follows the recommendation that every medical school should provide a single organized course, and should make it compulsory that every medical student should complete this course before taking a clinical examination which might qualify him for admission to the medical register. This would prevent the practice of taking qualifying diplomas not granted by universities (such as the Conjoint diploma, the diploma of the Society of Apothecaries, etc.) before the university course is completed. Some students, having obtained such a diploma, do not at present take their university degree in medicine at all. In London especially there is constant and detrimental competition between the University and the English Conjoint Board and the Society of Apothecaries. Only 5 per cent of the male students admitted by the University of London to take the university degree actually do take it as their first medical qualification, while 86 per cent register by means of the Conjoint diploma and only 45 per cent eventually take their university degree. A further recommendation is that the University of London should remodel its examinations so that these should reflect the aims and spirit of the training and should include more features of the 'internal' kind of examination, which is defined as an examination regulated by the university which trains the student who takes it and conducted by the student's own teachers in collaboration with external examiners. The latter, together with the inspectors of the General Medical Council, should safeguard the public interest. This suggested reform of the examinations held by the University of London also applies to the Universities of Oxford and Cambridge. A system of internal departmental examinations might complement and relieve the burden of these final examinations and encourage students to pay proper attention to all parts of the training.

Postgraduate training and research are dealt with in Part II of the report. Assuming that suitable central machinery should determine specialist status and that the specialist should first obtain general hospital experience, the report recommends that the intending specialist should be regarded as a trainee while he holds hospital appointments and should have sufficient time for reading and research and should be adequately paid. He should complete at least six months experience in general medicine and surgery as well as his pre-registration hospital experience. Watch should be kept for potential teachers among these intending specialists. There should be travelling fellowships for them, and nothing should debar a general practitioner from training to be a specialist. The most useful contribution of existing postgraduate medical schools would be to provide clinical appointments for specialist trainees. In Great Britain there is a singular lack of facilities for training specialists in hospitals dealing with special branches of medicine. Institutes dealing with these special subjects should be established, on a national plan, as departments of medical schools and universities based on large special hospitals. The Goodenough Committee's views on the education and status of specialists may be compared with those of the committee appointed by the General Medical Council to consider the registration of specialists, the report of which is summarized in the *British Medical Journal* (188; August 5, 1944).

Corresponding arrangements should be made for the training of specialists in pathology and public health; but adequate training in tropical medicine and hygiene cannot be obtained in Great Britain. After obtaining his theoretical and laboratory training in this subject here the intending specialist should hold approved hospital appointments abroad. Regular postgraduate study is required by practitioners, but refresher courses are only a short-term expedient and practitioners should be brought into regular association with the work of hospitals and of specialists by such means as clinical assistantships and personal associations. Refresher courses will, however, be necessary for many years and they should be specially designed for the practitioner. If it be decided that they should be compulsory, adequate financial arrangements will be needed similar to those embodied in the National Health Insurance scheme. The universities should organize these refresher courses and should approve teachers who give them. Such schemes of postgraduate education should be organized by a committee appointed by the university with a supervisor who would integrate his work with that of the Dean of the faculty of medicine. The exceptional resources of London as a centre of postgraduate education are not being utilized properly. The British Postgraduate Medical School should be an integral part of a postgraduate hospital centre in the inner area of London. This would seem to be impossible at present, but a satisfactory organization for postgraduate medical education can be created round the British Postgraduate Medical School on the basis of the Hammersmith (L.C.C.) Hospital and the existing special hospitals. These should be reconstituted as a federal organization with institutes dealing with the principal special subjects, and a scheme for this is outlined. The University of London should, however, like other universities also, appoint a committee on postgraduate medical studies. The award of postgraduate medical diplomas is also unsatisfactory. There are too many of these and the standards on which they are awarded vary considerably. They should all be awarded by the Royal Medical Colleges, excepting those given in public health, clinical pathology, bacteriology and tropical medicine, which should be awarded only by the universities providing the courses of instruction in these subjects.

Innumerable problems await research, and men with the ability for and impulse to do research must be found; they must be given favourable conditions for their work and the tools that they need. Young research workers should mainly recruit themselves, but they should be guided and given reasonable security in their careers. Scientific workers in fields other than medicine are required. The report reviews the work and methods of the Medical Research

Council and makes important proposals with regard to the provision of staff, accommodation and access to patients required for medical research. Basic research grants from public funds and others from private and public sources are required, and the Medical Research Council would be assisted if the funds granted to it by Parliament were determined annually.

Part III of the report deals with future financial requirements and with machinery for the distribution of Exchequer grants. The report must be consulted for details of these; but it may be noted that the University Grants Committee is given the responsibility for the distribution of basic research grants and Exchequer grants for educational facilities. It is suggested that this Committee, should appoint an advisory panel of persons with current experience of medical education and teaching hospitals.

# PHOTOCHEMISTRY IN RETROSPECT

By DR. T. IREDALE
University of Sydney

PHOTOCHEMISTRY now appears to be a well-established science with a highly developed technique of its own and an adequate foundation of theory, based largely on indisputable facts established by the molecular spectroscopist. Recent text-books[1] leave the reader in no doubt as to the correct avenues of approach to this subject. Its devotees must be prepared to undertake the detailed study of absorption spectroscopy, reaction kinetics, the behaviour of free radicals, and the electronic transitions in solids, some of which are still largely unexplored fields. The more serious student, however, will be disappointed to find that the historical approach to photochemistry has been greatly neglected in these books, excellent as they are in other respects. In the historical treatment of a science interesting sidelights are often shed on scientific method, and the lessons we can learn from them are of peculiar value. For example, it would be instructive to reveal why certain lines of investigation were dropped, how some apparently slight but fundamental observations led to developments of the greatest magnitude, why a fundamental law universally acclaimed and applied appears now to be worth only passing consideration. Photochemistry in particular, which has reached the greater part of its present stature within the last twenty years, has some interesting things to reveal which come within these categories.

During the nineteenth and early twentieth centuries, since the time of Grotthus and Draper, photochemistry made little real progress. The chemical interaction of light and matter was always a baffling mystery. Impetus to experimental work in certain directions was not lacking, because the sister science of photography was always confronted by problems which could not be solved by empirical methods alone. It was not in its applications, however, that photochemistry made its greatest progress.

Some of the most renowned investigations of three or four decades ago were concerned with the thermodynamic implications of photochemical change. This was a rational development, because light sometimes interfered with the laws of thermal equilibrium in a way which necessitated new assumptions and new theoretical treatment. In working along these lines investigators were not so fortunate, for while the chemical equilibria might be explained in general terms of free energy change, the mechanistic consequences of the light absorption itself were not properly understood, and highly speculative theories were put forward to account for this aspect of the phenomenon. This was before the advent of the quantum theory, or rather, before its immediate application, especially to problems of atomic structure.

In 1912 Einstein announced his well-known Law of the Photochemical Equivalence, derived from thermodynamical considerations of radiation equilibria, and later on deduced the same law, based on the Bohr model of the atom. Stark's idea of electron loosening in molecules, put forward some years before, had something in common with Einstein's generalization, which might have been a continued impetus to research, were it not for the fact that it was the exception, rather than the rule, for the law to be obeyed by any of the photochemical changes investigated from time to time. So far, indeed, has this law fallen from grace, that in one of the books previously cited, no mention whatever is made of it. One would not expect such an important landmark in the history of the subject to be relegated so soon to the limbo of forgotten things. The pioneering work carried out by Warburg, Bodenstein, Weigert, Bowen and others to test the efficacy of this law, when seen in its proper perspective, will be found to hold a very necessary place in the development of the subject.

In 1925, J. Franck[2], in a short exposition, correctly interpreted the relation between banded and continuous absorption spectra of diatomic gases, and brought to the photochemist the realization of the excited molecule as distinct photochemically from the normal or excited atom. This may be said to be the beginning of modern photochemistry as we know it to-day. On the spectroscopic side, the volume of research which followed immediately after Franck's discovery forms one of the most amazing chapters in modern physical chemistry. This much the photochemist could learn from it, at least about the simpler molecules he was accustomed to handle: he could deduce from the absorption spectrum what the light quantum did to the molecule. The subsequent complexities of chemical change were not always easy to follow, and sometimes assumed proportions which baffled the ingenuity of the most expert investigator. Thus it was that the light interaction part of a photochemical change, hitherto so elusive, became its most intelligible feature, the kinetics of the following-on reactions presenting much greater difficulties. But as the kinetics are merely bound up with final states of equilibrium, we must expect the last phase of photochemistry to be the standardization, thermodynamically, of the photo-stationary state.

The photochemistry of more complex molecules, apart from polymerization phenomena, has become largely the chemistry of free radicals, although prior to Paneth's instructive experiments in 1929, few investigators would have cared to be dogmatic about the existence of these short-lived intermediaries. The later work of Norrish, Pearson and others demonstrated beyond doubt the important part played by free radicals in photo-changes, albeit the behaviour of these radicals in the condensed (liquid)

phase has raised some new and at present unsolved problems.

The applications of photochemistry in the industrial sphere have been few and far between; this is not surprising, when one remembers that many chemical changes accelerated by light can also be carried out thermally, which is often the more economical method. Photochemists with their highly specialized technique are notoriously wasteful of light, employing, as they frequently do, narrow beams of the filtered radiation, utilizing only a fraction of the optical equivalent of the electrical energy expended in producing the light source. The most economical arrangement requires the light source to be in the centre of the reacting materials, so that the stray radiation is reduced to a minimum, which sometimes involves great practical difficulties.

A more profitable utilization of light may come about as the result of further exploitation of so-called electron transfer phenomena. Redox potentials, which are dependent on the activities of ions of variable valency, can be changed appreciably by absorption, by the ions, of light of great intensity, which is responsible for the electron transfer. The construction on the industrial scale of photo-galvanic cells working on these principles will be a problem for the electrochemist. In countries where sunlight is most abundant, there will be possibilities for much applied research along these lines.

## THE COSMIC TIME-SCALE

IN a series of recent mathematical papers, culminating in a general review of the subject in more physical terms[1], S. Chandrasekhar has laid the foundations of a statistical theory of stellar dynamics which treats the subject in a way fundamentally different from the ordinary analytical approach. Certain aspects of the theory concerning the dynamics of star clusters and the statistics of binary stars are discussed in detail by Chandrasekhar; they have interesting repercussions on current ideas concerning the time-scale of the universe, and are summarized below.

In this new statistical treatment, no attempt is made to follow in detail the history of any particular star in a gravitational assemblage: its motion is described in terms of a distribution function governing the probability of occurrence of a given velocity at a given time, the initial velocity being specified. The behaviour of each star is regarded as determined in part by the influence of the system as a whole and in part by the relatively rapid fluctuations produced in the local stellar distribution as the members of the system change their relative positions. Chandrasekhar shows[2] that, in an interval of time large compared with the average period of these fluctuations, their cumulative effect is to subject each star to a random acceleration and simultaneously to decelerate it in the direction of its motion by an amount proportional to the time interval. The effect of the near neighbours of a star is thus expressible in terms of a coefficient of diffusion and a coefficient of 'dynamical friction'. The latter term is chosen because the process operates only on stars in motion and it acts systematically as a brake on this motion. It can be shown that a dissipative force of this nature is necessary for the maintenance of a Maxwellian velocity distribution among the constituent stars.

The recognition of the part played by dynamical friction in the evolution of stellar clusters leads to important conclusions regarding the expectation of life of these systems. The technique of this new statistical dynamics can be used to calculate the probability that a star of given initial velocity will acquire (for the first time) another specified velocity at some later time. If for this second velocity we choose the velocity of escape from the cluster (twice the root-mean-square velocity of the stars) we have a means of estimating the rate at which a cluster disintegrates by impoverishment due to escape of its constituent stars. Chandrasekhar expresses[3] the probability $Q$ that a star will escape from a cluster during a time $t$ in the form

$$Q = 1 - e^{-t/t_0},$$

where $t_0$ is a function of the physical parameters (radius, central condensation, etc.) of the cluster. Taking $t_0$, in accordance with this expression, as a measure of the half-life of the cluster, and substituting the observed parameters for the Pleiades, he finds a half-life of $3 \times 10^9$ years. Now the Pleiades form a typical galactic cluster, one of many such which are presumably permanent or *quasi*-permanent features of the Milky Way system. In so far as we may identify the life-history of the Galaxy with that of its open clusters, then the half-life of the Galaxy is also of the order of $3 \times 10^9$ years. Moreover, if we adopt Chandrasekhar's definition[4] of the 'time-scale' of the Galaxy, namely, a natural unit of time during which the aspect of the Galaxy may be expected to change appreciably, then $3 \times 10^9$ years is this unit, whether the galactic clusters are permanent features of the system or products of some passing phase of cosmic evolution.

Further evidence regarding the time-scale of the universe comes from a study of the statistics of double stars. Until a few years ago it was believed that the observed frequency distribution of eccentricities among binaries showed that a condition of thermal equilibrium had been attained, and thus that the time-scale adopted for the Galaxy must be long enough ($\sim 10^{13}$ years) to allow establishment of equipartition among the parameters of a binary. It is now known[5], however, that the observed distribution, though a necessary, is not a sufficient condition for the existence of thermal equilibrium, and further, that other aspects of the data, particularly the distribution of energies or semi-major axes, are incompatible with equipartition. In itself this suggests that the time-scale cannot be so long as had previously been believed, and Chandrasekhar's new treatment[6] of the question confirms this. In this approach he examines the stability of a binary as it is affected by the differential effects produced on the components by the gravitational attraction of neighbouring stars. For any given separation between the two stars, there exists a distribution function governing the probability that forces differing by a specified amount will act simultaneously on the two components. In other words, a systematic differential acceleration governed by a definite probability law acts on the system so as to accelerate one star relative to the other. The rate of dissolution of a binary due

to this cause is calculated and shown to depend on the masses and separation of the components and on the local stellar density. In the neighbourhood of the sun, the time $\tau$ of disruption of a typical binary of semi-major axis $a$ astronomical units is shown to be

$$\tau = 2{\cdot}2 \times 10^{15}\, a^{-3/2} \text{ years,}$$

$\tau$ being the time needed to produce enough relative acceleration to make the kinetic energy of relative motion exceed the gravitational binding energy between the components. For separations in the range $10^3 - 10^4$ astronomical units, this formula gives times varying from $7 \times 10^{10}$ to $2 \times 10^9$ years. But observation shows that in this range statistical equilibrium has not yet been reached in the separations. That is to say, sufficient time has not yet elapsed for the fluctuating gravitational field even to modify appreciably the semi-major axes, much less to dissociate the systems. Here again, then, the time-scale indicated is of the order of a few thousand million years.

These investigations on the stability of star clusters and of binary stars reinforce the many other lines of evidence which point to a 'short' time-scale of $10^9$–$10^{10}$ years for the universe. The 'long' time-scale of $10^{12}$–$10^{13}$ years suggested, for example, by considerations of equipartition of translational energy among the stars, and by study of the evolution of moving clusters, finds less and less support among astronomers. Many of the arguments which seemed to demand it depend on mechanisms which, though they operate in one way now, may have operated quite differently in the early history of the universe. Gravitational interactions, for example, were possibly of a different order of magnitude then from what they are at present. The long time-scale is, indeed, appropriate if, as was thought likely some years ago, the energy-producing mechanism in stars is simple annihilation of matter; but the current theory identifying it with the synthesis of helium from hydrogen favours the short time-scale, and is the only one which has been made even remotely consistent with the facts at present known. Furthermore, direct measurements of the uranium/helium and uranium/lead ratios in pre-Cambrian rocks, and of the helium, uranium and thorium contents of iron meteorites[7], give ages ranging from 2 to $7 \times 10^9$ years. Again, if we accept the red-shift in the spectra of the extragalactic nebulæ as a velocity effect and extrapolate backwards using their present velocities, we find that they must have taken about $1{\cdot}8 \times 10^9$ years to reach their present positions.

This is no doubt a somewhat naïve approach to the subject, but in a very recent paper on the recession constant of the galaxies, Eddington concludes[8] that "the time-scale for the evolution of the universe is definitely less than $90 \times 10^9$ years, and I do not see much prospect of evading this limit". But all these lines of argument are not so conclusive that we can dismiss other methods of attack, and these recent researches of Chandrasekhar provide a valuable check on the currently accepted theory that the time-scale appropriate to the universe is the short one of $10^9$–$10^{10}$ years.

# OBITUARIES

## Sir Henry Lyons, F.R.S.

SIR HENRY LYONS was born in 1864: he was educated at Wellington and Woolwich and passed into the Royal Engineers in 1884; in 1896 he was appointed director-general of the Geological Survey, Egypt, and four years later director of the Survey Department of that country; during the War of 1914–18 he was commandant of the Meteorological Section R.E., and during 1916–18 he administered the London Meteorological Office; from 1919 until 1933 he was at first secretary and then keeper of the Science Museum, South Kensington. What a strange series of occupations: the army, geology, surveying, meteorology and museum management; yet it contains the key to his great and undoubted success, for it will be noticed that from the age of thirty-two years he was in charge of important Government departments. Lyons was first and foremost an organizer and administrator; he loved administration for its own sake, especially the administration of scientific organizations, but he was always ready to undertake administration of any kind so long as it involved reorganization and development.

Going to Egypt in 1896 as director-general of the small Geological Survey, he soon saw the need for a much more extensive survey, as little was then known with accuracy of the topography of the vast valley of the Nile and of the regime of the great river which flows through it. The Survey of Egypt was created, and Lyons organized it and directed it for eleven fruitful years. The valley was surveyed and the flow of the river scientifically measured; at the same time archæological remains, especially those to be submerged by the enlarged Aswan Dam, were studied and recorded. In 1906 Lyons published his book "The Physiography of the River Nile and its Basin", which reviewed all that was then known of the geology, climate and hydrology of the whole basin of the Nile. It is the most important scientific work on the Nile which has been produced up to the present time; it contains matter of the utmost importance for science and for the economy and government of Egypt. This work with other smaller publications earned for Lyons his position as one of the outstanding geophysicists and geographers of the British Empire. In 1909 Lyons returned home and lectured for a time on geography at Glasgow.

When war broke out in 1914, our army authorities had never even considered what meteorological help the army would need. The use of the aeroplane and the greater precision required by the artillery soon made it necessary to have a meteorological service at the front, and in 1916 it was decided to form a Meteorological Section of the Royal Engineers; and Lyons was put in charge as commandant. With Lyons' organizing ability in London and Ernest Gold's technical knowledge and immense drive in France, the new service was soon in full operation. By the end of the War the Meteorological Section R.E. had achieved a success which is not sufficiently known and appreciated. The experience and organization of the service built up in 1916 have been the foundations of the vastly increased meteorological service for the forces which is playing such a responsible part in the present War.

In 1916 Sir Napier Shaw, director of the Meteorological Office, found himself completely occupied with the preparation of meteorological information

required for the prosecution of the War; to relieve him Lyons took over the administration of the Office. He carried out the work with his usual ability for more than two years; but his period of service was too short and the conditions too abnormal for him to have left any permanent impression on the organization of the Office.

In 1920, after having served for a year as secretary, Lyons was appointed keeper of the Science Museum. Only those who knew the Science Museum in 1920 and were familiar with it just before the present War broke out can appreciate the great work carried out by Sir Henry Lyons at the Museum. In 1920 the Science Museum was a good museum, one of the best—if not the very best—of its kind in the world; but it was only a museum, governed by all the traditions of museum keeping and museum visiting. Lyons had no use for traditions; in fact the chief element in his success as an administrator was his willingness to break with traditions. Lyons wanted the museum to educate, and he knew that to do that the visitors must be interested. So every exhibit which could work was made to work, and if it could not work a working model was constructed in many cases. Life-size reproductions of famous workshops and laboratories were erected and demonstrations of modern scientific developments, such as radio and television, were arranged. Perhaps one of his most successful innovations was the series of demonstrations, accompanied by lectures and discussions, of new technical processes, such as the properties and manufacture of plastics. Instead of considering children a nuisance in a museum, he welcomed them and arranged one of the galleries especially for them. These are but a few examples of the changes made, but they illustrate the breath of life which Lyons breathed into the Museum. The Science Museum, while remaining one of London's greatest holiday attractions, has become one of its greatest educational institutions.

Lyons retired from the Science Museum in 1933 and was then free to devote himself to the voluntary work which had occupied so much of his time even while holding official posts. Varied as had been his official work, equally varied was the services he gave voluntarily to science and other interests. These probably occupied as much of his time, after returning to England in 1906, as his paid posts. It is quite impossible even to mention them all here, so I will confine myself to a few of which I had personal knowledge.

I first corresponded with Captain Lyons, as he then was, in 1913 or 1914, when I was engaged in India on writing up the meteorological results of Scott's Antarctic Expedition, 1910–12. As secretary to the committee appointed to publish the scientific results of the Expedition, Lyons was responsible for organizing the staff engaged on the work, and he supervised the printing and publication of the resulting books and monographs. It was a big undertaking and all of us engaged in the task were grateful to him for his helpful interest in our work. The imposing array of volumes containing the scientific records of the Expedition is a lasting monument to his disinterested zeal for science.

When I became director of the Meteorological Office in 1920, Lyons was one of the two representatives of the Royal Society on the Meteorological Office Committee, of which he was a member for twenty-three years (1918–41). The senior representative of the Royal Society is always the vice-chairman of the Committee (the Under-Secretary of State for Air being the permanent chairman) and generally presided at the meetings. Sir Henry became vice-chairman on the retirement of Sir Arthur Schuster in 1932. At the meetings and between meetings Lyons was always helpful; his short term as administrator of the Office had given him an insight into the difficulties with which the director has to contend, and his advice was always good and willingly given.

Sir Henry also succeeded Sir Arthur Schuster in 1928 in a much more important voluntary office, namely, the secretaryship of the International Council of Scientific Unions. It was a great piece of good fortune for international science that these two able Englishmen should have directed the work of the Council for the first eighteen years of its existence (1919–37). Lyons' great administrative ability, perfect command of the French language and unfailing good temper were valuable assets in guiding the Union through the difficult time between the two world wars, when international relationships were not easy.

The great work which Sir Henry has done for the Royal Society, as foreign secretary and treasurer, has been recorded by the president of the Royal Society (*The Times*, August 12). He was not just a good treasurer, he pulled to pieces and built anew the whole financial side of the Society's business. In this work his bent for science, his pride in the Society and his love of administration all found scope, and the result is worthy of a great Society and of a great administrator.

I cannot detail the work Lyons did for the Geological, Royal Geographical and Royal Meteorological Societies—he was a fellow of the first, a secretary of the second and president of the third; it is sufficient to say that he left his mark on all three. Needless to say he received many honours, including the Grand Cordon Medjidieh, 2nd class Osmanieh, Hon. D.Sc. Oxon., Hon. D.Sc. Dublin, F.R.S., knighthood (1926) and several medals awarded by scientific societies.

It was not, however, his great ability which endeared Lyons to those who came in contact with him; it was his utter absence of affectation, his friendly greetings and pleasant smile. Everyone who knew Lyons even slightly feels a loss in his death on August 10, and those of us who knew him well realize that we have lost a friend who cannot be replaced.

Sir Henry Lyons was the son of General T. C. Lyons, C.B., and married Helen Julia, eldest daughter of the late Mr. P. C. Hardwick in 1896. Lady Lyons was often with Sir Henry on his visits to international meetings and at official ceremonies, and was equally successful as hostess or guest. Our sympathy goes out to her and to their son and daughter in their great bereavement. G. C. SIMPSON.

---

WE regret to announce the following deaths:

Dr. Agnes Bluhm, an authority on social hygiene and heredity, of the Kaiser Wilhelm Institute for Biology, Berlin-Dahlem, aged eighty-one.

Mr. A. Deane-Butcher, C.B.E., formerly director-general of irrigation, Sudan and Southern Nile, on August 21, aged sixty.

Dr. Ethel Miles Thomas, formerly head of the Department of Botany in University College, Leicester, on August 29.

Sir Arthur Smith Woodward, F.R.S., keeper of geology in the British Museum (Natural History) during 1901–24, on September 2, aged eighty.

# NEWS and VIEWS

## Chair of Social Institutions, University of London

As announced in *Nature* of August 13, p. 206, Mr. T. H. Marshall has been appointed to the newly instituted University chair of social institutions tenable at the London School of Economics. This chair has a double function. Within the general field of sociology the professor will be responsible for promoting the study of modern social structure, which includes both analysis of the functions of social institutions and investigation into the character and composition of social groups. At the same time, Mr. Marshall succeeds Mr. C. M. Lloyd as head of the Social Science Department. This Department has grown steadily in size and range under Mr. Lloyd, and has been working to capacity throughout the War to meet the demand for trained social workers. But the development and expansion of the social services is likely to be even greater after the War, and universities will be under pressure to take more students and to train them more rapidly. In such circumstances great care will be needed to ensure that quality is not sacrificed to quantity, and to prevent any deviation from the twofold aim of raising the academic status of the Social Science Department within the University and raising the professional status of the trained social worker in the world outside. An important step in this direction can be made by integrating the work of the Social Science Department more closely with that of the other departments of the School. The dual character of the new chair should make this easier than it has been in the past. Mr. Marshall is at present reader in sociology in the School.

## Dr. James Philp

Dr. James Philp has been appointed director of research for the South African Wattle Growers' Union, Pietermaritzburg. He is also acting in an advisory capacity to the Forestry Division of the South African Government, with which he was previously engaged as its first forest geneticist. Dr. Philp was on the staff of the John Innes Horticultural Institution, Merton, until 1934, and during the succeeding eight years was in charge of the cereal division of the plant breeding section of the Egyptian Ministry of Agriculture.

## Medicine in Turkey

The July issue of the *Asiatic Review* contains an interesting article on the history of medicine in Turkey by Dr. H. Avri Aksel, chief surgeon to the Haseki Hospital, Istanbul, and a member of the Turkish Medical Mission which recently visited Great Britain. He points out that Turkish medicine, which has a history of six hundred years, is a continuation of the medicine of the Selcuk Turks who for centuries ruled in Anatolia and left a great many traces of their civilization. In the middle of the fourteenth century, the rapid expansion of the Turkish Empire and particularly the respect paid by the Sultans and their viziers to science and scientific men was the cause of Turkey being flooded by a great many men of science from Persia, Egypt, Irak and India. The number of hospitals increased and rose to fifty after the conquest of Istanbul. The medicine of the early days was very elementary, being rather a system of master and apprentice rather than a science taught in the schools, and knowledge was gained by practical experience.

The sixteenth century was the most brilliant age. Science and art reached great heights. Medicine was taught to students in well-organized courses, and for the first time lessons on anatomy were given. At the end of the seventeenth century, Turkish medicine gradually moved from the East and turned towards the West. Turkish medical men who went to Europe with the armies learnt European languages, translated important medical works into Turkish and introduced new methods. The eighteenth century was very important owing to the practice of inoculation against small-pox having begun in Turkey before it did in Europe. In the nineteenth century a big advance in surgery and medicine took place in Turkey. All the new methods employed in European medical colleges were applied. Anatomy for the first time was taught on the human body and a large library was established. There are now about two hundred hospitals in Turkey, innumerable maternity and child welfare centres, and a great many dispensaries and hospitals for infectious diseases and tuberculosis. There are altogether four thousand medical practitioners in private practice and in the service of the State.

## Carnegie United Kingdom Trust

The thirtieth annual report of the Carnegie United Kingdom Trust for the year 1943 (The Trust, Dunfermline) records a year of quiet progress and consolidation, the total grant expenditure showing, for the first time during the War, a decrease, from £69,000 to £62,000. This was due to the transfer to the Council for the Encouragement of Music and the Arts of financial responsibility for large orchestras and opera, the diminution or withdrawal of many of the salvage grants made early in the War, as well as of certain maintenance grants renewed on a diminishing scale, and the improved financial position of beneficiaries who have been offered grants on a deficiency basis. Grants for the equipment of youth clubs increased from £5,695 in 1942 to £9,178 in 1943; but conditions in the book trade have compelled the termination of the limited club library policy operated since 1940 for the benefit of new clubs. A preliminary report on an inquiry into conditions of unemployed young men in Liverpool, Glasgow and Cardiff was published in November under the title "Disinherited Youth", and a report on the Trust's bursary scheme for training youth leaders was also published during the year and circulated chiefly among central and local education authorities and voluntary organizations concerned with the welfare of young people. Grants were continued during 1943 in aid of the administration of the Land Settlement Association, the Museums Association, the National Council of Social Service, and the Rural Development Council of Northern Ireland as well as towards the maintenance of the three central libraries.

## Origins of Garden Vegetables

Vilmorin's production of biennial, red-rooted carrots from annual white-rooted wild plants, and Buckmaster's improvement of the wild parsnip, are two outstanding examples of vegetable introductions during the last century. These, and other interesting historical sketches of vegetable introduction, are detailed in a paper by W. F. Giles (*J. Roy. Hort. Soc.*, **69**, Pts. 5 and 6, May and June 1944). Peas apparently originated in the East; the Greeks grew the

crop in 300–400 B.C. Gerarde referred to several kinds of round-seeded pea at the end of the sixteenth century. It was not, however, until nearly two centuries later that Thomas Andrew Knight introduced the sweeter and more palatable varieties with wrinkled seeds. Scarlet runner beans were introduced from unknown antiquity in South America in 1633. Broad beans came from the East, their use there being of great known antiquity. The tomato was brought to Europe in the fifteenth century, but it has only been improved and attained popularity within the lifetime of our elders. Mr. Giles demonstrated the close affinity of various Brassicas with the wild *B. oleracea* by crosses, which all produced fertile hybrids of great morphological variability, but only incipient horticultural promise.

## New Contagious Disease in the United States

A NEW contagious disease with symptoms so mild the sickness may go unnoticed has recently been reported by Dr. Carl H. Smith, of Cornell University Medical College and the New York Hospital. The chief feature of the disease is an increase in the lymphocytes of the blood. Although the number of these white cells may be increased almost ten-fold, they are not abnormal. Fever and vomiting, pain in the back of the head and neck, or pain in the abdomen suggestive of appendicitis may occur in this new disease, but when they do, these symptoms last only a few days. In one case Dr. Smith reports, the child had fever, vomiting and abdominal pain, but a brother and sister had only symptoms of a mild cold. Only since 1939 have cases of this disease, called acute infectious lymphocytosis, been reported. The cause has not been identified, but is believed to be a virus. The disease apparently attacks young children chiefly, and they all seem to recover.

## Use of Inter-city Telephone Circuit for Television

ACCORDING to a recent announcement by the American Telephone and Telegraph Company (*Bell Lab. Rec.*, 22, No. 9; May 1944) plans have been made for the construction of a large amount of coaxial cable to be operated by radio relays. Tentatively, the coaxial extension plans call for the installation of 6,000–7,000 route miles of coaxial facilities in the next five or six years to help meet expected increasing demands for long-distance telephone service. These facilities would be suitable for interconnecting television stations for network operations. Work on the 295-mile Atlanta to Jacksonville route is in progress, and is expected to be in service for telephone purposes by the spring of 1945. Present coaxial equipment will provide television channels of 2,700,000 cycles in width. Tests have shown this equipment capable of transmitting the visual images with satisfactory clearness. Further technical improvements will make it possible to use a much wider band of frequencies, which will permit simultaneous use of the same coaxial for an improved (4,000,000 cycles) television channel and a large number of telephone messages.

The New York-Philadelphia cable, containing two coaxials, was installed in 1936 for further experiment. Its use for transmitting visual images for television broadcasts was first demonstrated in 1937. The cable recently has been providing telephone circuits. The first commercial installation was the Stevens Point-Minneapolis cable, containing four coaxials, two being in regular use and two in 'stand-by' use. This is capable of providing 480 telephone circuits with its present amplifiers. It is now equipped to handle nearly a hundred circuits and soon will be stepped up to about 150. One of the cables now in use between Philadelphia and Baltimore and another between Baltimore and Washington contain coaxials which, however, have not yet been equipped for service. The former contains six coaxials and the latter four. As many as six or eight coaxials are likely to be built into some of the new cables. In a six-coaxial cable, for example, with the present amplifying equipment, two coaxials could be used to provide 480 telephone circuits, another two could provide either two one-way television channels or 480 more telephone circuits, and the others would serve as equipped stand-by circuits to protect both services.

## Engineering Research in the U.S.S.R.

VOL. 1, No. 2 of the *Engineering Review* (Russian) (dated 1941) contains a collection of papers dealing with the mathematics of stress calculations for rotating disks, springs and conical shells. Other papers in the applied mechanics section describe very large mechanical testing machines and an electrical analogy for the investigation of torsion in bars. The hydrodynamics section has papers on filtration in non-homogeneous soils and the unsteady flow of water in canals. A short summary of each paper is given in English or German.

## Marine Water-Tube Boilers

A SERIES of papers read before the Institution of Naval Architects on May 10, 1944, dealt with the design of water-tube boilers for marine propulsion. Designs and data were submitted by Messrs. Babcock and Wilcox, Ltd., International Combustion Co., Ltd., La Mont Steam Generator, Ltd., and Yarrow and Co., Ltd., for a boiler plant suitable for a ship of 7,500 shaft h.p., using oil fuel. The complete set of papers provides a unique opportunity for direct comparison of the designs of modern boilers which should be of great value to marine engineers.

## Announcements

PROF. J. A. SCOTT WATSON, agricultural attaché at the British Embassy in Washington, has been appointed to the newly created post of chief education and advisory officer to the Ministry of Agriculture.

AT a recent meeting of the Geological Society of London, it was decided provisionally to admit persons between the ages of eighteen and twenty-three as junior associates. Such junior associates will enjoy most of the facilities offered by the Society, except that they may not attend discussions relating to the management of the Society's affairs, and they will not be entitled to vote at any meeting; they will not continue as junior associates after the close of the calendar year in which they become twenty-three.

MR. W. BOWEN, of the Bowen Instrument Co., Ltd., has made a gift of £5,000 to the Scientific Instrument Manufacturers' Association of Great Britain for the establishment of a fund to provide prizes for the best annual contribution to instrument research, development or design.

## Non-antigenicity of Gelatin

INTEREST in the inability of gelatin to act as a full antigen, that is, to produce specific anti-bodies when injected into an animal, has been revived by the observations of Haurowitz, Tunca and Schwerin[1], and also by the suggested use of isinglass for blood transfusion[2]. Haurowitz *et al.* find that whereas the intravenous injection of arsanil-azo-globulin into rabbits leads to the deposition of the bulk of the arsenic in the liver and bone-marrow[3], the injection of arsanil-azo-gelatin is followed by rapid excretion of the arsenic in the urine with very little deposition in the liver. The conclusions reached by these authors is that arsanil-azo-gelatin does not act as a full antigen because it is insufficiently deposited in the reticulo-endothelial cells of the body.

The non-antigenicity of gelatin may, however, be due to more than one factor, and at least four possible explanations have been or can be offered for the *in vivo* immunological inertness of this protein (cf. Wormall[4]), namely: (1) gelatin is relatively deficient in aromatic groupings; (2) it is deficient in carbohydrate groupings; (3) it may be rapidly excreted in the urine after intravenous injection into an animal; (4) it is usually prepared from collagen by prolonged treatment with boiling water or steam, and this treatment may well be sufficient to destroy any antigenic power of the preparation.

The introduction of aromatic groupings, including tyrosine, into gelatin does not produce a compound which has antigenic powers comparable with those of the majority of other proteins[5]. Thus, although some of these conjugated gelatin derivatives produce antibodies which react with the corresponding conjugates prepared from globulin and certain other proteins, these antibodies react very feebly or not at all with the gelatin derivatives; the results suggest that the non-antigenicity of gelatin is not due solely to lack of aromatic groupings. Similarly, the failure does not appear to be due solely to lack of tyrosine plus carbohydrate[6].

The third explanation given above receives strong support from the observations of Haurowitz and his colleagues, and it seems possible that the major part of injected gelatin or gelatin derivative is so rapidly excreted in the urine that little remains in the body to incite antibody formation. Gelatin and several other proteins with molecular weights less than 70,000 are rapidly excreted in the urine by anæsthetized cats and rabbits and by isolated perfused kidneys of dogs[7]. On the other hand, proteins such as egg albumin and the Bence-Jones protein, both of which are excreted by the kidney, are known to be fully antigenic; thus loss by excretion in the urine is probably not the only factor which determines the non-antigenicity of gelatin.

The fourth possible explanation can be excluded if it is shown conclusively that native collagen is non-antigenic, but unequivocal proof of this does not appear to be available. Glue is devoid of antigenic activity[8], and so is isinglass, "which is a collagen rather than a gelatin"[2]. Apart from these observations, however, it appears that little attention has been given to the parent protein as distinct from the partially hydrolysed product, gelatin. It would seem desirable that a more complete immunological study should be made of the antigenic properties of the natural unhydrolized collagens. Such an investigation might certainly help to throw some light on the vexed problem of the antigenicity of proteins.

## Capacity of Hyaluronidase to Increase the Fertilizing Power of Sperm

THE capacity of hyaluronidase to liquefy the highly viscous gel which cements the cumulus cells around the unfertilized tubal egg of the rat was described by McClean and Rowlands[1], and confirmed in the mouse by Fekete and Duran-Reynals[2] shortly afterwards. We suggested that the gel is hyaluronic acid similar to that in synovial fluid and, to enable its disintegration to occur as a preliminary to fertilization, a certain unspecified concentration of hyaluronidase must be established by the sperm in the vicinity of the egg. The fact that intromission of such a large number of sperm is necessary to ensure fertilization, therefore, may well be related not only to the safe passage of one or more sperm into the Fallopian tube but also, and possibly more especially, to the establishment of this requisite concentration of enzyme. Some preliminary experiments, which are described below, have now been carried out in rabbits to investigate the capacity of hyaluronidase to increase the fertilizing power of dilute sperm suspensions.

Ovulation was induced in Dutch and Himalayan rabbits by intravenous injection of 50 I.U. of chorionic gonadotrophin. A mixed sample of semen from 8–12 rabbits was collected in an artificial vagina and its sperm-count estimated using a Zeiss hæmocytometer. The semen was then diluted in Baker's[3] solution so as to contain $2 \times 10^7$ sperm per c.c., and from this were then prepared (1) further dilutions to give suspensions of sperm varying between $2 \times 10^6$ to $2 \times 10^4$ per c.c., and (2) a hyaluronidase-containing filtrate of the sperm, the latter having been inactivated by heating at 50° C. for 5 min. and separated by vigorous centrifugation. This sperm-free filtrate was then mixed in equal proportions with the various sperm suspensions and 2 c.c. of the mixtures inseminated artificially into each rabbit at approximately 7 hr. after the injection of gonadotrophin, that is, 4 hr. before the expected time of ovulation. Sperm counts were again made wherever practicable on the inseminates. The amount of hyaluronidase in the semen, and when possible also in the inseminates, was estimated by its capacity to prevent the appear-

ance of a mucin clot on the addition of acetic acid to a freshly made substrate containing 1 per cent horse serum albumin and 0·25 per cent of a standard preparation of potassium hyaluronate extracted from human umbilical cord. Enzyme activity is expressed in mucin clot prevention (m.c.p.) units. Details of the assay method have been published by McClean[4]. Filtrates of $2 \times 10^7$ sperm were found to contain 4–8 m.c.p. units per c.c.

Fertilization was determined by the presence of multi-cellular ova in washings of the Fallopian tube examined under a dissecting microscope. The rabbits were killed 36 hr. after ovulation when the normal fertilized egg consists of 8–16 blastomeres. The expected number of eggs can be ascertained by counting the number of ovulated follicles in the corresponding ovary; the full complement was almost invariably recovered. A normal rate of segmentation was observed, so that unicellular eggs were, therefore, considered to be infertile.

In all, seven experiments, as outlined above, were made. Two of these were carried out to determine the approximate number of sperm necessary for fertilization. The results, which agree well with the observations of Walton[5], indicate that for maximum fertility $1 \times 10^6$ or more sperm are required, that only a small number of eggs become fertilized when the inseminate contains $2 \times 10^5$ sperm, and that $1 \times 10^5$ sperm are probably incapable of causing fertilization. The approximate median effective concentration of sperm varies from $4{\cdot}47 \times 10^5$ to $1{\cdot}82 \times 10^6$. Of five experiments in which hyaluronidase (filtrates of $2 \times 10^7$ sperm) was added to the inseminates, four showed that the enzyme was effective in increasing fertility. In these four experiments the median effective concentration of sperm varied between $5{\cdot}44 \times 10^4$ and $1{\cdot}52 \times 10^5$. In one experiment hyaluronidase was ineffective. Inseminates containing $2 \times 10^4$ sperm with added enzyme were found to be incapable of causing fertilization. Taken together, the tests show that although the action of hyaluronidase is very variable under the conditions tested, it increased the fertilizing capacity on the average to the extent that treated groups required about one sixth of the sperm concentration to give a 50 per cent response, compared with that in control groups. The range covered was, however, from one thirtieth to equality of concentration in different tests. The probability that the enzyme in fact facilitates fertilization is of the order of at least 50 to 1 in favour.

At this stage of the investigation any discussion as to the method by which the enzyme, even in the absence of a vector, reaches the Fallopian tube would be purely speculative. A rapid spreading action of the enzyme through the lumen of the female reproductive tract similar to that through the skin and subcutaneous tissue would, however, seem to be ruled out by the unpublished observation of McClean that hyaluronidase does not lower the viscosity of cervical mucin. If one assumes, therefore, that this enzyme does not assist in the conveyance of sperm, these experiments incidentally may throw some light on the number of sperm required to be inseminated in order that one or more may reach the Fallopian tube. It is possible that not one of those in the inseminate containing $2 \times 10^4$ sperm reaches the tube, and that the number of those in the inseminate estimated to contain $1 \times 10^5$ that do, in the absence of added enzyme, is so small that the concentration of hyaluronidase they are able to establish locally is not sufficient to liquefy the gel protecting the egg.

Further investigations are now proceeding into the role of this enzyme in fertilization and its relationship to infertility associated with oligospermia.

## Abrasion of Soil Insects

IN a recent preliminary note[1], evidence was given to show that abrasion of the superficial layer of wax on the epicuticle would go far to explain the action of inert dusts in causing insects to dry up; and confirmation of these ideas was published by Kalmus[2].

It may be of interest to point out that the permeability of insect larvæ living in the soil can be similarly explained by the abrasion of the cuticle by soil particles. Larvæ of Hepialus and Agrotis, Pterostichus, Agriotes, Aphodius and Phyllopertha, Bibio and Tipula when treated with ammoniacal silver all show obvious scratches. In the caterpillars Hepialus and Agrotis, the scratches occur chiefly on the prominent folds along the sides of the body and the outer surfaces of the true legs. In the scarabaeids Aphodius and Phyllopertha it is the lateral folds, the terminal segment and the rounded back that are most scratched. In the larva of the carabid Pterostichus, the sclerites show many longitudinal scratches; the soft intervening cuticle may be almost uniformly abraded except where it is thrown into depressed folds.

In the wireworm Agriotes, the rate of water-loss varies in direct proportion with the degree of visible scratching. But if the wireworm is allowed to moult out of contact with the soil, it is found to possess a cuticle impermeable to water like that of other

PART OF THE CUTICLE OF A WIREWORM TREATED WITH AMMONIACAL SILVER. REDUCTION BY THE EXPOSED PHENOLS REVEALS THE EXTENSIVE SCRATCHING OF THE SURFACE.

insects. Thus at 20° C. the average rate of evaporation from the wireworm into dry air is about 10·5 mgm. per sq. cm. per hour. In a larva kept out of contact with the soil for ten days after moulting, the rate was 0·4 mgm. per sq. cm. per hour. These observations will account for the fact that the normal wireworm cuticle, though highly hydrophobe, is readily permeable to water[3]. They may have a bearing on the entry of insecticides through the cuticle of soil insects[4].

## Paracrinkle Virus and Inheritance

IN his recent interesting article[1], Dr. Darlington speculates on the origin of viruses and in particular on that of paracrinkle virus in the potato variety King Edward. He states with reference to paracrinkle that "what is a stable and presumably useful cell protein with one plant genotype acts as a destructive agent with another"; also that "any virus that can be transmitted only by grafting must therefore have arisen from grafting; that is to say, from the invasion of one plant by the proteins of another". We gather from this that Dr. Darlington considers that a protein constituent of King Edward becomes a virus on transference by grafting to another potato variety. While this is a tempting speculation, whatever evidence there is does not support it, and we should like to point out the following facts.

First, unlike the plasmagenes, the paracrinkle virus is not transmitted through the seed. Thus, twenty-two seedlings from the cross King Edward female × Flourball were tested by grafting on Arran Victory, and in no case was the paracrinkle virus present in the seedlings. Paracrinkle thus behaves like the majority of plant viruses and not like a plasmagene.

Secondly, paracrinkle can be transmitted by grafting to certain potato varieties which carry it without symptoms, for example, President. From such infected President plants other susceptible varieties such as Arran Victory can also be infected in series.

There thus seems no fundamental difference in the reaction of King Edward to paracrinkle virus from that of any other 'carrier' variety to the virus 'carried'.

## The Melanic Form of *Rattus norvegicus* in London

RECORDS of the melanic form of *Rattus norvegicus* from various parts of the British Isles have been published since Thompson[1] in 1837 first described it as a new species under the name of *Mus hibernicus*. There is very little information about the frequency of melanism at any time in the wild population, and it is therefore impossible to draw an accurate picture of changes taking place in the status of the two forms in recent years. The matter is of interest from an evolutionary aspect, and also from the point of view of rodent control, where, since it is necessary to distinguish between colonies of the black rat, *R. rattus*, and those of the brown rat, *R. norvegicus*, it is desirable to know of the existence and status of melanism in the latter species.

The melanic form is superficially very similar to the black rat, *R. rattus rattus*. It is very dark brown, almost black in colour; but unlike the black rat, which is distinctly paler on the belly than on the back, it is scarcely noticeably lighter on the underside. Some individuals have a white patch on the chest or belly; but this varies considerably in size and shape. In all its structural characters it is identical with *R. norvegicus* and can easily be distinguished from *R. rattus rattus* by the small ears, short tail and absence of long guard hairs on the back.

I examined a sample of the rats caught in the Port of London during the two years Sept. 1941–Sept. 1943, together with a number from a large riverside factory in Woolwich in the second of these two years. The majority of these rats were *R. rattus*, but the sample included 1,266 *R. norvegicus*. The sample was drawn from the six dock areas: the London and St. Katharine Docks, the Surrey Commercial Docks, Regent's Canal Dock, the India and Millwall Docks, the Royal Docks, and Tilbury Dock, as well as from the factory already mentioned. These may fairly be considered as a representative section of the riverside districts of London, so that these rats may be said to constitute a fair sample of the rodent population of this district. They are all, with the exception of Tilbury, which is outside London, surrounded by warehouses, bombed sites and dwelling-houses which are typical of this riverside, and the rodents' environment is probably similar throughout the area.

| Locality (riverside) | No. of *R. norvegicus* examined | No. of melanics found |
|---|---|---|
| London and St. Katharine Docks .. | 115 | 2 |
| Surrey Commercial Docks .. .. | 337 | 0 |
| Regent's Canal Dock .. .. | 138 | 4 |
| India and Millwall Docks .. .. | 98 | 1 |
| Royal Docks .. .. .. | 406 | 11 |
| Woolwich factory .. .. .. | 90 | 2 |
| Tilbury Dock .. .. .. | 82 | 1 |
| Total .. .. .. .. | 1,266 | 21 |

The percentage of melanics in the sample as a whole was 1·66 per cent.

The melanics appear to be uniformly distributed along the riverside. The figures were examined for homogeneity by P. H. Leslie; the variation in the proportion of melanics between the different areas is not in any case significant, and is compatible with variations in random sampling ($\chi^2 = 10{\cdot}25$, $n = 6$, $P = 0{\cdot}20$–$0{\cdot}10$).

Melanic brown rats have also been obtained during the last five years from the following places: Bethnal Green[2], Tooting, Bishopsgate, City Road[3], Leadenhall Market[4], and Dagenham[5], as well as one I found

in the Isle of Dogs. It seems likely that melanism is widely spread throughout the London area.

An incidence of melanism as high as 1·66 per cent cannot be accounted for by mutation and recombination alone. The factors responsible for the appearance of this character must, therefore, be well established in the rat population of this district. Earlier records of the occurrence of the variety in London seem to be practically non-existent. This suggests that the black variety must have appeared here quite recently; if this is so, it is unlikely that a balance has yet been struck between the two phases. *R. norvegicus* is probably in a state of transient dimorphism. Confirmation of this must, however, depend on this work being repeated at some future date.

Little is known about the general distribution and status of the melanic phase in the past. The scanty literature on the subject has been summarized by Barrett-Hamilton[6] and Millais[7]. It is possible that local museums may have a certain number of unrecorded skins in their collections.

I am much indebted to Dr. M. T. Morgan, medical officer of the Port of London Health Authority, for his co-operation and help, and to Dr. Arthur Davies of the Seamen's Hospital Society for his kindness in providing laboratory facilities; and I wish to acknowledge their interest throughout this investigation.

## A Ciliate from the Dead Sea

A piece of flint-stone, 7 × 7 × 5 cm., was taken by Dr. T. Rayss on August 24, 1940, from the bottom of the Dead Sea near Kalliah from a depth of c. 150 cm. of water and handed to me. On the stone, brown spots and vein-like markings were seen, and when some of the material scraped from the veins was examined microscopically, brown cells of a blue-green alga were observed. The following day the stone was submerged in Dead Sea water of s.g. 1·1875, in a closed glass vessel and exposed to light near the window. It was left standing for three years and four months, during which time no visible change in colour was noticed. However, in the meantime, owing to very slight evaporation, the specific gravity of the water rose to 1·2026, and when once again a hanging drop was microscopically examined, four different types of micro-organisms were revealed. These were identified as follows:

(1) *Aphanocapsa* sp. Cells of a blue-green alga, 3·4 μ × 5–10 μ, appearing singly, in pairs or clumps, and were similar to those previously seen on the stone and found in mud samples from the bed of the Dead Sea[1].

(2) *Dunaliella viridis* Teod. Green flagellates, 2·7 μ × 8–11 μ, varying somewhat from their usual shape, previously described[2], due, no doubt, to the increase in salt concentration. Both flagella arise laterally, one overlaps the anterior end, while the other with which the organism moves extends down beyond the posterior end of the cell.

A ciliate grown in Dead Sea water. Unstained preparation. × 800.

(3) *Amœbæ*. Cells 6–16 μ × 6–27 μ, showing a granulated content, short pseudopodia and slow motility. It still remains to be ascertained whether the organisms are identical with the species of Dimastigamœba previously described[1].

(4) *Ciliate*. Oval shape, 8–13 μ × 16–24 μ, transparent, colourless and having four longitudinal ridges. The organism is very actively motile. The cilia extend around the cell, and two long spines appear at the posterior end. Vacuoles are present; nucleus and cytostome are not visible (see accompanying photograph).

The four different types of organisms were obtained in liquid culture media, exposed to light, containing: 15 per cent salt, 0·03 per cent $Ca(NO_3)_2$, 0·01 per cent $KH_2PO_4$, 0·02 per cent peptone and traces of $FeCl_3$.

The amœbæ and the ciliate were grown in the dark at 30° C., in a semi-solid agar media consisting of the same liquid media plus 0·6 per cent agar; a small amount of sterile rice starch was added after inoculation.

It is of interest to note that the green flagellates, from only one out of a number of liquid cultures normally grown in the light, completely lost their green colour when grown in a semi-solid agar medium in the dark, and so far have failed to regain their colour when re-exposed to light.

Recently, flint-gravel and water of s.g. 1·1848, collected from the shore of the Dead Sea, was exposed to light. After two weeks a number of the green flagellate *Dunaliella viridis* Teod. and a few amœbæ were observed.

Including the ciliate found actively growing in Dead Sea water, the different groups of organisms which have now been found in the Dead Sea are: bacteria, several blue-green algæ, two species of green flagellates, amœba (possibly more than one species), and a ciliate.

Full details will be published elsewhere.

I take this opportunity to thank Dr. T. Rayss, of the Hebrew University, Jerusalem, for the flint-stone she gave me.

## Manganese-deficient Soils

IN 1942, Sherman, McHargue and Hodgkiss[1] described a modification of Leeper's[2] method which would identify: (a) manganese-deficient neutral and alkaline soils; (b) strongly acid soils that will become manganese-deficient when limed to near neutrality; and (c) soils that are likely to contain such excessive quantities of available manganese as to be toxic to plants. There is evidence from analyses of English soils that their method may be useful at any rate in identifying the first two classes of soils.

The method described by the above-mentioned authors was slightly modified to ensure easy manipulation and to save time by the use of separate 20-gm. samples of air-dried soil for the three extractions, namely: (1) water-soluble manganese, (2) exchangeable manganese, and (3) easily reducible manganese. This procedure was adopted instead of the single sample used successively for the three extractions. It will be seen from the results that the small quantities of water-soluble and exchangeable manganese in the extract containing the easily reducible manganese made no difference to the general conclusions. The three samples were then shaken for one hour in a rotary shaker with 150 ml. of extracting agents, that is, distilled water, neutral ammonium acetate, and 0·2 per cent solution of hydroquinone in neutral ammonium acetate. The procedure as described by the authors was then followed.

Three types of soil were investigated:

(1) A light, black, heath soil from Shropshire with a strongly acid reaction under natural conditions.

(2) A heavy Lias clay from south Warwickshire with an almost neutral reaction.

(3) A garden loam from the grounds of the University of Birmingham with a *p*H above 7·0.

Manganese-deficient oats were seen growing on the first two soils while healthy oats were growing on the University soils. The Shropshire soils had *p*H values between 6·4 and 7·9 due to heavy liming, and certainly fall into the category manganese-deficient when heavily limed. The Lias soil from Warwickshire had *p*H values between 6·3 and 7·0 and is therefore an almost neutral soil. The high *p*H of the University soil was due to heavy liming.

MANGANESE IN P.P.M. OF AIR-DRIED SOIL

| Source | *p*H | Water soluble | Exchangeable | Easily reducible |
|---|---|---|---|---|
| Shropshire 1 | 6·7 | 1·2 | 1·1 | 8·2 |
| ,, 2 | 6·4 | 0·0 | 1·5 | 5·7 |
| ,, 3 | 7·9 | 0·0 | 0·8 | 5·3 |
| ,, 4 | — | 0·5 | 0·8 | 2·8 |
| Warwickshire 1 | 6·5 | 0·0 | 4·7 | 33·1 |
| ,, 2 | 6·3 | 0·0 | 1·3 | 25·6 |
| ,, 3 | 7·0 | — | 12·3 | 43·7 |
| University 1 | 7·5 | 0·0 | 2·7 | 183·0 |
| ,, 2 | 7·7 | 0·5 | 2·1 | 120·0 |
| ,, 3 | — | 1·5 | 8·9 | 98·2 |
| ,, 4 | — | 1·1 | 9·3 | 113·7 |
| ,, 5 | — | 0·8 | 10·5 | 150·0 |

It is seen from the accompanying table that the easily reducible manganese is the important fraction in identifying manganese-deficient soils. The Shropshire soil had an easily reducible manganese of less than 10 p.p.m., the neutral Lias clay had less than 50 p.p.m. manganese, while the University soil samples all had about or well over 100 p.p.m. of manganese. There is, therefore, further evidence here supporting the conclusion of Sherman, McHargue and Hodgkiss that manganese-deficient soils can be identified by this method.

A survey of soils is of course necessary to establish this method, but should it prove to give results consistent with those of Sherman, McHargue and Hodgkiss and those mentioned here, the method would certainly prove to be useful in advisory work.

## Science and the Fisheries

THIS is truly a subject for the *formidable* speculation with which Prof. James Ritchie has treated it[1]. He dreams of a mountainous, nay astronomical, dash of nutrient chemicals in the North Sea, which is to make a remarkable increase in the growth of fish. And why not ? Greater changes than that have been made on the face of the earth in the past; but scarcely so simply—except in destruction. The southern, shallower part of the North Sea, where the main nurseries are, has been found to suffer from shortage of phosphate in one or two dry years, and there was no shortage in one or two normal years. Sun and warmth are likely limiting factors. In the meantime, transplantation has been successful in increasing fish-growth, on an experimental scale in the North Sea, and on a commercial scale in the Belt Seas.

The rosy picture given of the United States as the land of the free, in freshwater fishery matters, does not now apply to salmon fisheries, nor I think to many other fisheries of a commercial scale. I dislike the word 'restriction': 'moderation' is a better one, and is part of the practice of husbandry.

## A New Barium-feldspar from Wales

DR. A. W. GROVES recently sent to one of us a specimen of white vein-material found in the manganese ore from the Benallt mine near Rhiw, Carnarvonshire. He suspected the presence of the rare barium-feldspars celsian and paracelsian, which were discovered in the same mine in 1911[1,2]. We found the optical properties of the mineral differed from those of any known barium mineral, and microchemical analysis has now shown that it is a new barium-feldspar and the first example of an alumino-silicate of barium containing sodium as the dominant alkali. The name proposed for the new mineral is 'banalsite', suggested by its chemical formula $BaNa_2Al_4Si_4O_{16}$.

X-ray photographs show that banalsite is orthorhombic with unit-cell dimensions *a* 8·50, *b* 9·97, *c* 16·73 A. and space-group *Iba* or *Ibam*; the observed specific gravity is $d_4^{16} = 3{\cdot}06$, whence the unit cell contents are calculated to be $4BaNa_2Al_4Si_4O_{16}$. No crystal forms are visible on hand specimens, but thin sections reveal indications of a few faces of simple indexes including (110) and (001) both parallel to good cleavage directions. The optic axial

plane of the mineral is parallel to (100), $\alpha = c$, refractive indexes $\alpha = 1{\cdot}5695$, $\beta = 1{\cdot}5710$, $\gamma = 1{\cdot}5775 \pm 0{\cdot}0005$ (sodium light). The optic axial angle measured on the universal stage is $2V$ 41° positive. Face-centred cells can be derived from the unit cells of banalsite and sanidine, which have similar dimensions, probably indicating the similarity of the silicon-aluminium-oxygen network in the two structures.

The banalsite occurs massive associated with tephroite, alleghanyite, jacobsite, baryte and calcite in certain rare veinlets and narrow bands in dark purple manganese ore. The tephroite and alleghanyite form thin blade-like crystals showing parallel intergrowths. The orientation of the crystals in these intergrowths and the chemical and X-ray study confirm A. F. Rogers's work[3] on alleghanyite from North Carolina, which showed that alleghanyite is the manganese analogue of chondrodite, and that it bears the same relation to tephroite as chondrodite does to forsterite.

## α-Tungsten

IN the course of an examination of the coatings formed on the tungsten electrodes of a spark gap and of a film sputtered from the electrodes on to the walls of a glass container, it has been found that both the coatings and the film contained a considerable proportion of α-tungsten in addition to normal body-centred cubic tungsten.

This observation is of interest since the only previously reported occurrence of α-tungsten is in the product from certain methods of electrolytic extraction[1,2]. So far as is known, these are not in commercial use, and the tungsten electrodes themselves did not contain any of the α-form.

Identification was based on the X-ray diffraction pattern. The specimens gave sharp lines, and the cell size, absent spectra and the relative intensities observed for the permitted lines agreed with the published structure[1].

The lattice parameter, measured in a 19-cm.-diameter powder camera, was found to be $5{\cdot}0408 \pm 0{\cdot}0002$ kX. at 18° C., compared with the previously reported value of $5{\cdot}038 \pm 0{\cdot}003$ kX. at 20° C.[3].

Subsequent to this examination it was found that Mr. H. P. Rooksby had also made observations of certain occurrences of α-tungsten, and these form the subject of the accompanying communication.

N. J. PETCH.

[2] Burgers and Van Liempt, *Rec. Trav. Chim.*, **50**, 1051 (1931).
[3] Neuburger, *Z. Krist.*, **85**, 232 (1933).

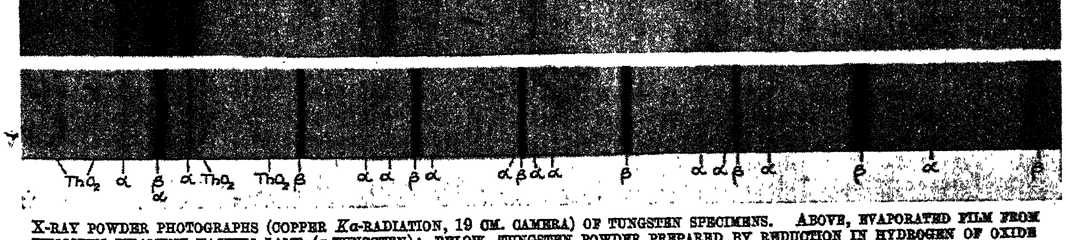
MR. N. J. PETCH has found that the α-form of tungsten occurs in sputtered films and deposits, whereas the only previously reported occurrence was in specimens prepared by electrolytic extraction.

We have also observed this second form of tungsten in the course of examination by X-ray methods of specimens of metallic tungsten from various sources. For example, α-tungsten is often the major constituent of films deposited on the glass envelopes of certain types of vacuum lamps, by evaporation from the tungsten filament. In some instances the α-form appears to be the sole constituent of the volatilized film, but in others it occurs mixed with the normal body-centred cubic form. Phosphorus is usually employed in the lamps that have been examined, for perfecting the vacuum conditions, and it is possible that this has some influence on the structure of the deposited tungsten. No definite evidence which would indicate the effect of the presence of phosphorus is, however, available at present.

Invariably the crystal size of the deposits is so small that the lines of an X-ray powder photograph are diffuse, but even so a sufficient number of reflexions are present for decisive identification of the α-phase. A typical powder photograph of an evaporated tungsten film consisting wholly of the α-phase is shown in the reproduction below.

We have also on occasion noticed the second form of tungsten in powders prepared by reduction of oxide in hydrogen. It has never been found in high concentration in such powders, and the exact conditions of reduction causing its retention have not been explored. But it does appear that impurities such as thoria have some influence. When small percentages of thoria (of the order of 1–2 per cent) are present, the α-phase has been detected in powders that have been reduced at as high a temperature as 800° C., whereas 650° C. has been given as the transition temperature for α-tungsten prepared by electrolytic processes.

The X-ray reflexions for the α-phase in reduced metal powders are sharp, and measurements of the lattice constant give $5{\cdot}041 \pm 0{\cdot}0005$ kX., in very



X-RAY POWDER PHOTOGRAPHS (COPPER $K\alpha$-RADIATION, 19 CM. CAMERA) OF TUNGSTEN SPECIMENS. ABOVE, EVAPORATED FILM FROM TUNGSTEN FILAMENT VACUUM LAMP (α-TUNGSTEN); BELOW, TUNGSTEN POWDER PREPARED BY REDUCTION IN HYDROGEN OF OXIDE CONTAINING 2 PER CENT THORIA (MIXTURE OF β- AND α-TUNGSTEN).

close agreement with Mr. Petch's determination. The X-ray photograph of a tungsten powder containing a proportion of the α-phase is also reproduced in the illustration.

It is apparent from the results described by Mr. Petch and ourselves that the α-form of tungsten may be produced in several ways besides that of electrolytic extraction, namely, by sputtering, by volatilization or evaporation, and, in certain circumstances, by reduction of oxide in hydrogen. The temperature of deposition (or reduction) is probably an important factor in determining the proportion of α-tungsten formed, but the evidence from the examination of volatilized films and reduced powders suggests that impurities such as phosphorus and thoria may also take some part.

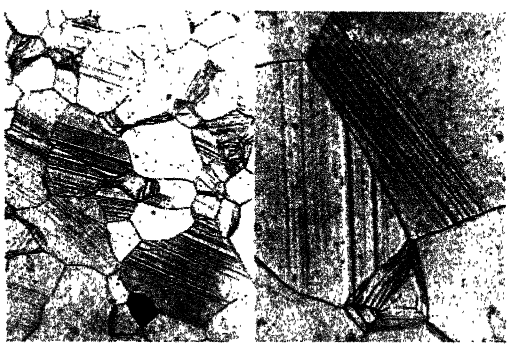
## Thermal Fatigue of Metals

IN our recent communication[1] the photographs as reproduced were placed in the wrong order, so the lettering on them should read *d c b a*—not *a b c d*. There is a progressive *increase* in the deformation and in the grain boundary migration as the number of thermal cycles is increased.

The deformation, as indicated by the formation of slip lines, and the grain boundary migration, are shown more clearly in the accompanying photograph. This illustrates at two different magnifications the numerous slip lines and the grain boundary migration produced in a cadmium specimen after ten very slow cycles between 30° C. and 150° C. The electrolytically polished specimen, which initially was almost free from slip lines, was immersed in an oil bath, and was heated and cooled with it, the duration of a cycle being approximately seven hours. This was done in order to avoid internal stresses due to rapid temperature changes.



(*a*) (*b*)

DEFORMATION IN PURE CADMIUM AFTER 10 SLOW CYCLES BETWEEN 30° C. AND 150° C. (*a*) × 100; (*b*) × 500.

Experiments carried out since our earlier communication have confirmed the view that the deformation observed after cyclic thermal treatment is due to the anisotropy of thermal expansion in the crystals of non-cubic metals.

X-ray back-reflexion photographs show that the lattice distortions produced by the deformation remain in the metal and accumulate as the number of cycles is increased. This is the case for zinc, cadmium and even tin, although in the latter metal the outward signs of deformation are less than in zinc and cadmium. In some cases, recovery occurs after a large number of cycles.

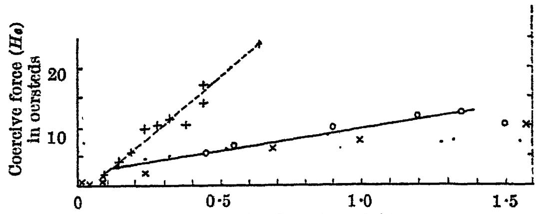
## Relationship between Coercive Force and Carbon Content of Plain Carbon Steels

THE straight-line relation between the coercive force and the carbon content of plain carbon steels has been observed by many investigators. The question arises how far can the relation be carried. The data published by authorities such as Benedicks, Metallografiska Institutet, Stockholm, and Cheney, U.S. Bureau of Standards, have been collected in the International Critical Tables[1]. They used samples containing very small amounts of silicon, manganese, sulphur and other impurities. If their results are plotted we obtain a straight line as shown in Fig. 1.



., Cheney; ○, Benedicks; ×, Gumlich; +, annealed, 850° C.

Fig. 1.

Carbon enters into iron forming pearlite, a structure which can be distinguished from ferrite (iron) under the microscope, when the concentration is more than 0·008 per cent. The amount of pearlite increases as the carbon in iron is increased. If we plot the percentages of pearlite against the coercive forces of the annealed specimens, we obtain the result shown in Fig. 2. The formation of pearlite is complete when the carbon content reaches 0·83 per cent; that is, the eutectoid. After passing the eutectoid, cementite comes into play.

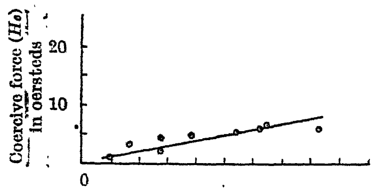


Fig. 2.

When the steel is in a quenched state, the relationship of the coercive force becomes more complicated. It depends on the quenching temperature and the cooling medium. The results from Gumlich are redrawn in Fig. 3.

Recently various applications have been found in this relationship between the coercive force and the carbon content. The instrument, which is known as

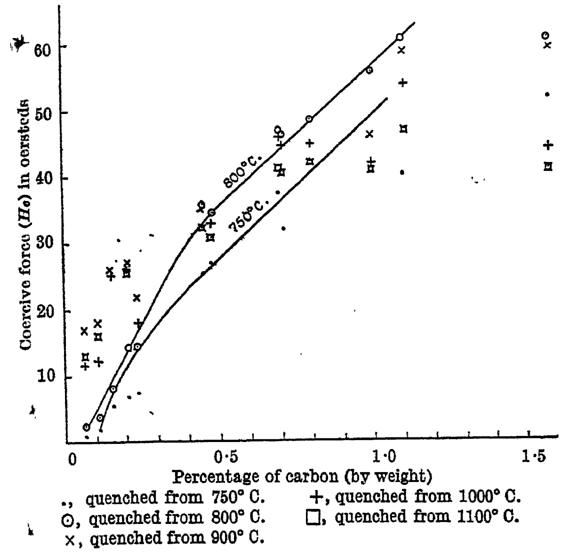

Fig. 3.

a coercimeter, used for the rapid determination of carbon in open-hearth steels, designed by Rogers[2] and his collaborators, may be mentioned as one example. The curve given by them is not explained theoretically, perhaps because the quenching temperature could not easily be controlled. When we compare the curve of Rogers with the curves of Fig. 3, the best quenching temperature range is 800–850° C. This may be taken as the standard range whenever the coercimeter is used in the steel-works.

Many investigators have attempted to correlate the coercivity with the mechanical properties of steels. Metallurgists like Mathews[3] have laid much emphasis on the hardness but have found little success. From the formula

$$H_{c\,\max.} \simeq 3/2.\lambda\sigma_i/I_s$$

derived by Becker[4], I think that the tensile strength is a good measure of the internal strain of the polycrystalline material. The tensile strengths in kgm./mm.² of carbon steels are therefore plotted along the dotted line in Fig. 1. Only those steels in an annealed state and containing low percentages of manganese and silicon are selected[5]. It seems that there is a parallel relation between the tensile strength and coercivity of the ferromagnetic material.

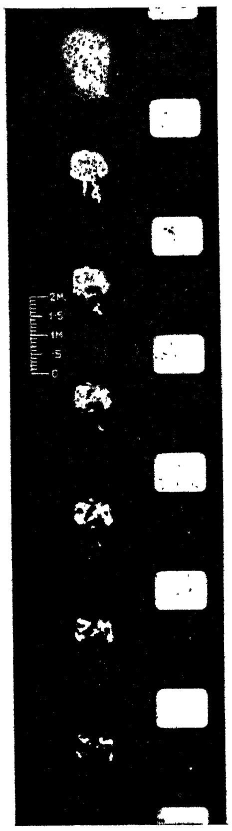
## Persistence of Luminosity in Air

Protracted luminosity occurs naturally in air in at least two forms—aurora borealis and ball lightning. In the case of the aurora, a widely accepted theory is available to account for the energy input which causes excitation. There is, however, considerable doubt as to the corresponding energy mechanism which has been presumed to be necessary to account for the strange stability of ball lightning.

The question arises as to what extent it is necessary to postulate an energy source to explain the sustained luminosity which follows an electrical discharge in air and lasts long enough to be noted by a casual observer. The possibility seems to exist that such a phenomenon can in certain circumstances be described adequately as a purely dissipative process which is simply the aftermath of an intense discharge. The laboratory phenomenon of afterglow is a well-known example of the latter process, as negligible energy is put into the gas by the electrical circuit during the afterglow time. Most of the work on afterglow has been carried out at low pressures where durations of several minutes have been observed, but Meek and Craggs[1] have recently shown that afterglow lasting approximately 30 microsec. can be produced in argon at atmospheric pressure.



EXTINCTION OF 10 KV., 280 AMP. ARC AT NIGHT

In a previous communication[2] the appearance of luminous clouds as a sequel to arc extinction was reported. This aspect of arc extinction has now been examined further, and cloud durations varying from approximately 0·1 to 0·3 sec. have been measured. This phenomenon seems to be a form of afterglow which has some resemblance to ball lightning. It was observed in seven separate tests with currents varying from 90 to 320 amp. at 10,000 volts. Great dissimilarities have been noted in regard to the number, shape and rate of shrinkage of the luminous clouds. Some of the tests were carried out at night and recorded by means of a cine-camera which was used without a light filter. A section of the film is reproduced here; in this the arc current is considered to have ceased between the first and second frames from the top. The camera speed was 32 frames per second.

This work indicates that the energy dissipation following a heavy electrical discharge in air can be arranged to take place so as to provide luminous masses of gas which persist for an appreciable fraction of a second. It is not unreasonable to expect that in certain cases the phenomenon can be observed with the naked eye.

# RECONSTRUCTION IN WALES

THE first interim report of the Welsh Reconstruction Advisory Council, appointed on June 30, 1942, "to survey, in conformity with the general examination of reconstruction problems now being conducted by the Government, those problems of reconstruction which are of special application to Wales and Monmouthshire, and to advise on them", which has now been issued by the Minister of Reconstruction*, emphasizes that its inquiry is in the nature more of a continuous survey than of an exhaustive examination of specific subjects. The report records the Council's considered opinion as to the state of affairs likely to emerge in Wales after the conclusion of the present War, together with an outline of the kind of measures which will be required in any comprehensive plan for the economic and social rehabilitation and development of the region. It includes a survey of the field already covered by the Council during its first year's work and an indication of the nature of the work which remains to be done.

The first part of the report includes a historical retrospect which emphasizes that the Welsh people claim that experience of the past shows that plans must be made in advance as an essential part of the war effort. The Committee is also insistent that this matter of preparation for the future should not be dissociated from the life of the people affected by entrusting the whole task to any remote central body of experts. In broad outline, at least, such planning must be the function, if not of the people themselves, at any rate of those who know the needs of the people and of the areas.

This part of the report, which clearly owes something to the "Second Industrial Survey of South Wales", makes five major assumptions which underlie all the Council's discussions and recommendations: (*a*) that the War will result in a victory for the United Nations; (*b*) that the War against Germany will end first and hostilities will consequently taper off rather than cease abruptly; (*c*) that sooner or later there will be in Great Britain as a whole, and in Wales in particular, a considerable body of labour to be re-absorbed into peace-time occupations, and an economic situation of sufficient difficulty to demand exceptional measures, planned in advance; (*d*) that the Government's policy will be directed primarily to the maintenance of a high level of employment; and (*e*) that for a considerable period after the end of the War sufficient control will be maintained over the disposition of essential raw materials, plant and equipment, labour supplies (including demobilization) and the utilization and construction of factory premises to avoid the worst excesses of a 'first come, first served' scramble.

The post-war demand for labour in Wales will be determined by the future course of international trade and by the nature and extent of the home market demand. Certain further assumptions are made with regard to both these factors, and the report then emphasizes that there are other fundamental questions of national policy which will condition any regional plan and concerning which any assumptions are unwise in the absence of decisions by the Government. For example, in regard to planning, the interests of Wales will not be served unless the central planning authority to be established accepts and acts upon the principle of decentralization and devolves very large powers upon regional bodies, the activities of which will be co-ordinated by the central authority. Any new Welsh regional economic planning authority must be organized along lines that are at once flexible and powerful.

Reviewing the five phases through which post-war reconstruction in Great Britain as a whole may be expected to pass—momentary dislocation, first reconstruction boom, general prosperity, turn of the tide, and second reconstruction effort—the Council points out that the greatest danger of the first boom period is that it will encourage in Wales an attitude of complacency, leading to the deferment of thought about the need for fundamental changes in the basic industries (or even the denial of the need for them), together with a failure to take urgent steps to broaden the industrial basis. It also emphasizes the strictly temporary nature of war-time prosperity in Wales: between forty and fifty per cent of all the workers employed by new industries in a large sample area covering nearly half the population of Wales were shown in two recent surveys to be attached to establishments which must almost inevitably either close down or drastically curtail their activities at the end of the War.

Furthermore, there are four potential danger spots which are discussed in some detail. The first of these is the possibility that technological unemployment consequent upon the introduction of strip-mill methods of production in the tin-plate industry at Ebbw Vale, and the necessity to adopt such methods in the west central and western anthracite areas will lead to the emergence of a new set of depressed areas. This is an industry in which there is every reason to anticipate drastic reorganization, rationalization and considerable technological unemployment. It would be fatal to oppose a technical development which has become a necessity if the competitive power of the Welsh industry in world markets is to be maintained, but the Council recommends that careful regard should be had to any means whereby the old works can be used as subsidiary to the new strip mills. The necessary reorganization and concentration will also require agreement between the interests concerned, and this may present difficulties unless undertaken as part of the post-war reconstruction plans.

The second danger is that insufficient thought may be given to the need to make provision in the mining industry for the situation likely to be caused by the post-war closure of uneconomic pits and the early exhaustion of others. For this reason the Council recommends as a matter of urgency that all necessary steps be taken to ensure the availability of a survey of coal resources with the view of deciding the most suitable locations for development. The third danger lies in the existence in a number of areas of former mining and metallurgical townships which have completely lost their basic industry and now serve only as dormitories for workers travelling long distances to strictly temporary war factories. The fourth is the probability of a considerable volume of unemployability in certain areas. A full examination of this problem must be an essential part of any social security scheme which the Government may introduce.

The second part of the report discusses the work of the Council from June 30, 1942 to December 17, 1943. In its survey of industry the report, after

* Office of the Minister of Reconstruction. Welsh Reconstruction Advisory Council. First Interim Report. Pp. 132. (London: H.M. Stationery Office, 1944.) 2*s*. net.

stressing the necessity of securing an early expansion of the export trade in Welsh coal and recommending early steps to remove inequalities such as royalties and wayleave rents, urges that the Government should support mechanical firing as an alternative to oil for tramp and liner tonnage, and that the Board of Admiralty should consider its adoption, where practicable, in naval tonnage. Wales, however, may need an integrated coal-oil-power-and-chemical industry, developed as a whole, the keys to which lie in an abundant supply of cheap electricity and an extensive programme of research. Reviewing production of oil from coal, the Council recommends an early re-examination of the Fischer-Tropsch process in the light of changed circumstances, and the establishment of a trial plant in Wales after the War. It also seems desirable that further experience of low-temperature carbonization should be gained in Wales by allowing the plant already erected there to come into operation at the earliest possible moment after the War, while it is for consideration whether the whole question of the production of oil from coal is not one which cannot be dealt with satisfactorily within the structure of private enterprise.

In regard to the slate industry, the Council recommends immediate consideration of its place in relation to the post-war building programme, while attention is also directed to the particularly useful part which the refugee firms set up in Wales could play in the rehabilitation of the devastated countries of Europe. An adequate expansion of the tourist and holiday industry in Wales is conditional upon an improvement in communications to break down its relative inaccessibility, and the highest importance is attached to the provision of a trunk road from north to south Wales, passing through the beautiful but isolated centre of Wales, and to the early provision of a road crossing over the River Severn. The provision of better road communications across the Severn below Gloucester should be announced as part of the Government's reconstruction programme, the various schemes which have been put forward to be reviewed immediately by technical experts, and all road improvements on each side of the Severn should be related to the new means of communication. Establishment of at least one trans-Atlantic aerial terminus in Wales, suitably linked with the major road and railway routes, is also recommended.

The development of the tourist industry is recognized as demanding more study, research and planning than the Council has yet been able to give to it, and after endorsing the recommendations of the Scott Committee on this matter, the Council urges that at least one area in North Wales and one in South Wales should be developed as national parks at the earliest suitable moment after the War, with assistance from public funds if necessary.

The Council further emphasizes that Wales needs to explore very fully the potentialities of a marriage between industry and agriculture. Agriculture, the producers' goods industries, the consumers' goods industries and the tourist industry are all interdependent, and the expansion of each in Wales could, properly organized and co-ordinated, benefit all. General measures are also required to increase the industrial attractiveness of Wales—the provision of buildings of standard design, in advance of demand, on selected suitable sites, widely distributed, and the clearing and levelling of every site which, in the opinion of the regional planning authority, it is desirable to use for industrial purposes, are two suggested measures—while the provision of electric power at an exceptionally low cost is a fundamental requirement for many industries. Here the Council inclines to the establishment of a special Welsh electrical development board. Refitting of dairy farms is one of the most urgent of Welsh post-war agricultural problems, while in many areas there is room for substantial improvement in the general level of cleanliness and hygiene in milk distribution. In regard to grassland and ley farming, a comprehensive examination of the whole position in the light of long-term requirements, and in terms of the quantities of equipment and fertilizers that would be required, as well as of the problems of finance and land ownership that would be raised is desirable. The importance of a long-term policy of afforestation is also stressed, as well as the suitability of Wales for timber-growing; special study of the types of trees best suited for planting in different parts of Wales is recommended. Stress is also laid on the improvement of facilities for technical education, in which co-operation between industrialists and educational authorities and between the local authorities themselves is essential. In this respect the Council, commenting on the White Paper on Education, regards it as unfortunate that rearrangements should be made within the present structure for one service without reference to the general problem of the reorganization of local government as a whole.

# THE FATIGUE OF GLASS UNDER STRESS

By E. OROWAN

Cavendish Laboratory, Cambridge

GLASS under stress shows a characteristic fatigue phenomenon of practical importance: it can be broken by stresses far below its ordinary breaking stress as measured in short-time tests, provided that the load is applied for a sufficiently long time. About one third of the short-time breaking stress is sufficient to produce fracture if it is sustained for a number of weeks. In contrast to metals, the stress need not fluctuate periodically in order to develop this fatigue phenomenon, of which the most spectacular everyday manifestation is the sudden spontaneous cracking of glasses or bottles under internal stresses which they may have withstood for many years.

As with metals, the practically important question is whether a 'safe stress' exists; that is to say, whether there is a stress limit below which the glass can stand up to the load indefinitely. Extensive experimental work has been carried out on the dependence of the time of breaking upon the breaking stress, and the latest investigations[1,2] seem to lead to a relationship between these quantities that can be represented approximately by a straight line if both stress and time are plotted logarithmically. If extrapolation to longer times is justified, this would mean that no safe stress exists, and, therefore, glass would be an essentially unreliable material for use under sustained loads.

In a recent issue of *Nature*[3], J. B. Murgatroyd has discussed this phenomenon. In his view, the influence of the duration of loading is "not easily explicable by Griffith's theory alone", and he suggests an explanation based on the assumption that glass consists of "an elastic matrix which contains small pockets of

'quasi-viscous' material". This model is then worked out mathematically, and a certain agreement is found with the measurements just mentioned; unfortunately, however, the basic equation used to express the strain in the viscous elements is incorrect, and this has the effect of invalidating the conclusions. The relationship between stress $S_v$, strain $\sigma$, time $t$, and coefficient of viscosity $\eta$ for a viscous rod under tension is $S_v = 3\ \eta\ \frac{d\sigma}{dt}$, not $S_v = \eta\sigma/t$. The correct mathematical treatment of Murgatroyd's model leads to the existence of a maximum and a minimum value for the strength, reached asymptotically for very short and very long breaking times, instead of the straight line in his Fig. 2. In order to explain, for example, a ratio 3·3 between short-time strength and long-time strength, it would be necessary to assume that in any cross-section only 30 per cent of the area corresponds to the elastic matrix which alone is capable of taking up a sustained stress, and 70 per cent to the material of the viscous pockets, which on this hypothesis would constitute the greater part of glass.

My purpose here is to show that the decrease of the breaking stress with increasing duration of loading can be explained on the basis of the Griffith theory without *ad hoc* assumptions, and that in this way the ratio of the breaking stresses for very short and very long duration of loading can be calculated, in reasonable agreement with experiments. It will be seen that, in the absence of other causes of fatigue, this explanation demands the existence of a safe stress roughly equal to a third of the short-time strength. It suggests that, on extending the duration of loading beyond the range so far investigated, the logarithmic strength – time curve would bend away from the inclined straight line and go over asymptotically into a horizontal line, corresponding to constant strength for very long times of breaking.

Griffith's expression for the tensile strength $k$ of a brittle isotropic solid is

$$k = \sqrt{\frac{2\ \alpha\ E}{\pi c}},$$

where $E$ is Young's modulus, $c$ the depth of the most dangerous surface crack, and $\alpha$ the surface energy. Now it has been found by Obreimow[4] that the surface energy of mica, if measured by cleaving in vacuum, is about ten times higher than in air. According to measurements I have made[5], the surface energy of mica is 4,500 erg/cm.$^2$ in vacuum and 375 erg/cm.$^2$ in air. Owing to the chemical similarity between mica and glass, a similar ratio may be expected for the latter. If the adsorbed film of air or moisture that is responsible for the reduced value of the surface energy in air can penetrate to the bottom of the crack, this value must be used in the Griffith formula when the material is broken in air, and the higher vacuum value when the tensile test is performed in vacuum. According to the Griffith formula, the tensile strength is then about $\sqrt{4500/375} = 3{\cdot}5$ times higher in vacuum than in air[6]. In fact, Schurkow[7] has found that the strength of silica glass fibres, baked out and broken in vacuum, is 3·5–4·5 times higher than in air.

If fracture occurs after a very short time, the adsorbed film cannot follow the propagation of the crack from the surface zone into the interior; the cleavage surfaces created by the crack propagation will then be clean, and the stress necessary to produce such rapid fracture is obtained from the Griffith formula by using the vacuum value of the surface energy. If, on the other hand, the crack deepens very slowly, the adsorbed film has time to diffuse to the bottom of the crack and reduce the surface energy to the lower value corresponding to cleavage in air. The ratio of the breaking stresses for very rapid and very slow fracture, according to the Griffith formula, is then equal to the square root of the ratio of the surface energies in vacuum and in air, which is about 3·5 if it is permissible to use for glass the ratio obtained with mica. This agrees well with the results of Preston[3], who found that the breaking stress increased 3·2-fold as the breaking time was reduced from $10^5$ to $10^{-2}$ sec. Holland and Turner[1] investigated glass strips in bending; here the breaking stress for rapid loading was about 3·3 times higher than the stress under which all specimens broke within 1,000 hours.

It seems, therefore, that the rate of diffusion of adsorbed matter into the Griffith crack may account quantitatively for the influence of the duration of loading upon the breaking stress. If this explanation be correct, glass should have a safe stress limit below which it would stand loading indefinitely, and this safe limit should be reached in practice in the long-duration tests of Holland and Turner and of Preston. The question whether or not the straight-line relationship breaks down for extremely long breaking times calls for further investigation; this may prove very difficult because, during the test, surface corrosion and devitrification may occur, and their effect may mask the one to be studied.

If the fatigue effect is mainly due to the finite rate of diffusion of the adsorbed film in the crack, certain characteristic phenomena should be expected. First, short-time strength and long-time strength should be equal if the test is performed in vacuum on specimens baked out in vacuum, and they should further be equal to the limiting short-time strength in air. Secondly, specimens that have been subjected for a length of time to a stress exceeding the safe long-time strength, but released before fracture occurs, should show reduced strength in short-time tests, for the following reason. Under a stress that is lower than the short-time strength but higher than the safe stress, the most dangerous surface cracks are propagated slowly, at a rate that is determined by the rate of diffusion of the adsorbed matter. When they reach the depth at which, according to the Griffith formula, further propagation under the given load becomes possible with the vacuum value of the surface energy, sudden fracture occurs. If the loading is interrupted before this happens, the cracks will nevertheless be deepened, and the short-time strength of the specimen reduced.

If the adsorption – diffusion effect is the main cause of the fatigue, it should be possible to increase the resistance of glassy materials to long-sustained loads by covering the surface with a sufficiently inert and impermeable varnish, or by a glaze of which the coefficient of thermal expansion is lower than that of the bulk. For similar reasons, the decrease of the breaking stress with increasing duration of loading should be slower with toughened glass, in which the surface layer is under compressive stress; here the surface cracks are either altogether ineffective, or at least the diffusion of atmospheric matter into them is made slower by the compression of the cracks at the surface.

The viscosity of the glass cannot be expected to influence the strength except at temperatures where the viscous deformation is of noticeable magnitude.

Its influence, however, would be opposite to what is observed with glass at room temperature. Viscous deformation makes the bottom of the cracks less sharp, and thus raises the strength by reducing stress concentrations. An increase of the tensile strength with temperature in the region of incipient plasticity has, in fact, been observed on colophonium and colophonium - shellac mixtures by Hauser[8]. Prolonged action of stress, therefore, would make the specimen stronger, not weaker, so far as the viscosity effect alone is concerned.

# NATIONAL INSTITUTE OF ECONOMIC AND SOCIAL RESEARCH

THE annual report of the National Institute of Economic and Social Research for 1943 is of exceptional interest. In addition to a general report and a report on research in 1943, the report on the library and equipment and the usual list of publications and of research staff at December 31, 1943, it includes a discussion of the Institute's research policy, which is of considerable general interest in relation to the statement in the White Paper on Employment policy of the Government's intention to establish a permanent central staff qualified to measure and analyse economic trends and to call for more quantitative information from industry on current economic movements.

Originally it was anticipated that the proper field of the Institute's work would lie mainly in the measurement of changes, the discovery of trends and the analysis of structure, and its first inquiries were directed to the measurement of the national income in Great Britain, the economic problems of nutrition, the extent and distribution of unemployment and the location of industry. The systematic study of these subjects has now been taken over by Government departments with resources that no private agency could command, although the Institute has been able to supplement official studies by its own studies of the national income, consumption and other subjects.

The Institute's resources have also been fully occupied during the War on related inquiries, and the accelerated extension of realistic and statistical studies in the social sciences due to the War has led to the Institute being approached not only by Government departments and academic workers, but also by business men and their associations, with suggestions for research or requests for assistance in organizing research. Although the War has incidentally added largely to the small number of research workers experienced in realistic and statistical investigation, the need for such study will be as great for a time when hostilities cease as during the War, and the resources of the Institute are likely to be strained by the demands made on them. Even when an authoritarian direction of industry is removed, an exact and comprehensive, constantly adjusted analysis of resources and requirements will remain necessary as a basis both for Government policy and private business decisions.

Economists and other students of the social sciences will find themselves faced, therefore, with demands for guidance which will be unprecedented in scale if not in character. Even when the analysis is dictated by a theoretical approach, the post-war need will be the statement of problems in realistic and quantitative terms. For this, mechanical aids as well as the resources of specialized library and adequate secretarial staff will be essential, and such resources the Institute hopes to provide on a greater scale in future. Calling in the co-operation of experts in different fields, it can promote and arrange for the direction of inquiries and provide the personnel and material aids for their execution. It will endeavour to develop a part of the field itself, and will co-operate with individual students and other agencies working in the same or connected fields; but apart from a small portion of its funds held ready to meet requests for assistance from individual scholars, the bulk of the Institute's resources should be concentrated on one field where there is a prospect of achieving definite results without serious overlapping with the activities of the research departments of the universities.

The executive committee of the Institute has now reached the conclusion that this main effort should be directed to work on the structure and productivity of the national economy in Britain. In its simplest form the object is to examine the way in which wealth is created in Great Britain, to inquire what determines the amount of wealth created in the average man-hour of British labour, how it compares with other countries, what underlies the differences, what causes the gradual increase and what could be done to accelerate it. Two major projects now in train fit naturally into this framework. The statistical inquiry into the national expenditure, output, and income of the United Kingdom in the years between the Wars provides the essential basic data, and the co-operative inquiry into the distribution of the products of industry is an attempt to see how far existing data shed light on these questions. The Institute would also hope to supplement these inquiries with detailed factual inquiries into the experience of specific British industries, directed particularly to the relation of costs and efficiency and to comparisons with industries in other countries.

The general report refers to the circulation of the first issue of the Register of Research in the Social Sciences, which continues to be prepared by the secretary as editor, with the assistance of the editorial advisory committee appointed by the Consultative Conference on the Social Sciences. The Institute has continued to provide facilities for the activities of the National Service Committee for Social, Economic and Statistical Research, and this Committee is preparing a memorandum on the post-war position of the education and employment of economists at the request of Lord Hankey's Interdepartmental Committee on Further Training and Education.

Most of the research work during the year represented the continuation of programmes already in progress, but the Institute took under its wing the inquiries initiated by Mr. R. Titmuss into "Disease Mortality and its Changing Distribution in England

and Wales" and the statistical inquiry into "Methods of Investigating Oscillatory Movements in Time-series" by Mr. M. Kendall. Dr. A. Baykov's study on "The Development of the Soviet Economic System" was enlarged, and final work on its preparation for the press substantially completed. M. N. Momtchiloff's study of the financial and economic experience of south-eastern European countries was published early in 1944 under the title "Ten Years of Controlled Trade in South-Eastern Europe". The programme of work on local taxation studies undertaken by Prof. and Mrs. Hicks was modified, a study on wealth and poverty in local government being postponed in favour of two 'occasional papers', one of which, "Problems of Valuation for Rating", is in the press and the other, "The Incidence of Local Taxation in England and Wales", was awaiting comment by certain Government departments at the end of the year.

Besides the two major inquiries in progress already mentioned, that by Miss P. M. Deane on "The Measurement of National Income of Selected Colonial Territories" was also continued, but at the end of the year the inquiry into aspects of commercial policy was suspended. An investigation into the economic effects of advertising was started in the middle of the year, and M. N. Momtchiloff began work on a new inquiry into the monetary position of the six south-eastern States of Europe. In the spring, a grant was made to the University of Birmingham in support of Prof. Sargent Florence's inquiry, "Location and Optimum Size of Plants in Particular Industries", which is intended to test the hypothesis that there is an important relation between the size of an industry's plant and its location pattern.

Some further details of the research work of the Institute are given this year in a new Publications and Programmes pamphlet which, in addition to listing studies and occasional papers already published and publications now in the press, includes an account of some of the programmes of research on which those publications are based, and also of other publications in active preparation. Among these may be mentioned the study, "Personal Expenditure on Consumption in the United Kingdom, 1920–1938", and the occasional paper, "The Structure of Money Flow Systems", both coming from the major programme of research into national expenditure, output and income directed by Mr. R. Stone; two occasional papers, "Productivity, Prices and Distribution in Selected British Industries" and "International Comparisons of Productivity, Cost Ratios and Share of Wages in British, American and German Manufacturing Production" under the Distribution of the Product of Industry inquiry; and A. Collier's "The Crofter Problem: A Study of Economic and Social Conditions in the Highlands and Islands of Scotland".

## FORTHCOMING EVENTS

### Wednesday, September 13

BRITISH ASSOCIATION OF CHEMISTS (LONDON SECTION) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. H. W. Rowell: "The Development of Plastics".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DIRECTOR OF THE BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION—The Chairman of Council, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1 (marked 'Personal') (September 15).

ASSISTANT DAIRY BACTERIOLOGIST (temporary)—The Registrar, The University, Leeds (September 15).

SPEECH THERAPIST—The Director of Education, Education Offices, 15 John Street, Sunderland (September 15).

TEACHER (full-time) OF MATHEMATICS in the Nautical College Department of the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool (September 15).

SPEECH THERAPIST (full-time)—The Director of Education, Hamilton Square, Birkenhead (September 15).

ASSISTANT (full-time) to teach either MECHANICAL ENGINEERING or ELECTRICAL ENGINEERING SUBJECTS in the Stockton-on-Tees Technical School and Evening Institute—The Director of Education, Shire Hall, Durham (September 16).

SENIOR SPEECH THERAPIST—The Director of Education, Education Offices, Nelson Square, Bolton, Lancs. (September 16).

LECTURER IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, Loughborough College, Loughborough (September 18).

UNIVERSITY READERSHIP IN CHEMISTRY tenable at the Royal Cancer Hospital (Free)—The Academic Registrar, University of London, South Kensington, London, S.W.7 (September 18).

POULTRY PATHOLOGIST for the New Zealand Department of Agriculture—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 18).

SPEECH THERAPIST (full-time)—The Director of Education, Education Offices, Wolverhampton (September 18).

ASSISTANT LECTURER IN MATHEMATICS—The Secretary and Registrar, The University, Bristol (September 20).

BOROUGH ENGINEER AND SURVEYOR—The Town Clerk, Town Hall, Walworth Road, London, S.E.17 (endorsed 'Borough Engineer and Surveyor') (September 22).

ASSISTANT REGISTRAR—The Registrar, The University, Sheffield 10 (September 23).

LECTURER (full-time) IN MECHANICAL ENGINEERING—The Principal, Battersea Polytechnic, Battersea, London, S.W.11 (September 23).

LECTURER IN VERTEBRATE ZOOLOGY—The Secretary, The University, Edinburgh (September 25).

LECTURERS (2) IN MECHANICAL ENGINEERING, and a LECTURER IN ELECTRICAL ENGINEERING—The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15 (September 25).

PHYSICIST (must have first-class experience on problems relating to Lighting and Aircraft and Automobile Lamps) for a Company in Birmingham—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.630.XA) (September 26).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

CHAIR OF BIOLOGY in Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 30).

PRINCIPAL OF THE HACKNEY TECHNICAL INSTITUTE, and PRINCIPAL OF THE SOUTH-EAST LONDON TECHNICAL INSTITUTE—The Education Officer (T.1), County Hall, Westminster Bridge, London, S.E.1 (September 30).

PRINCIPAL OF THE WALKER TECHNICAL COLLEGE, Oakengates—The Secretary for Education, County Buildings, Shrewsbury, Shropshire (September 30).

PROFESSOR OF PHYSICS—The Registrar, University College, Singleton Park, Swansea (October 18).

HONOURS GRADUATE IN CHEMISTRY (London, Reference No. F.2719.XA), HONOURS GRADUATES (2) IN METALLURGY (Neath, Reference No. F.2720.XA; Shipley, Reference No. F.2721.XA), and HONOURS GRADUATE IN CHEMISTRY or Member of the Royal Institute of Chemistry, Branch E (London, Reference No. F.2722.XA), on the research staff of a progressive National Organization with home and overseas interests—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (October 21).

LIBRARIAN—The Librarian, Queen's University, Belfast (October 31).

CHAIR OF PSYCHOLOGY in the University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (October 31).

BEYER CHAIR OF ENGINEERING—The Registrar, The University, Manchester 13 (November 18).

AGRICULTURAL SCIENTIST with intimate knowledge of livestock and breeding problems in this country, to take charge of the Board's Livestock Improvement Department—Milk Marketing Board, Livestock Improvement Department, Thames Ditton, Surrey.

CHIEF INSPECTOR (must have had first-class experience in Inspection of Steel and Non-Ferrous Products, and have full knowledge of A.I.D. procedure) by large Steel Foundry in Yorkshire—The Ministry of Labour and National Service, Appointments Office, The White Building, Fitzalan Square, Sheffield 1 (quoting Reference No. 107).

REFRIGERATING ENGINEER for West Africa—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 1162).

HEAD OF THE ENGINEERING DEPARTMENT—The Principal, Technical Institute and Secondary School, Dursley, Glos.

GRADUATE (temporary, man or woman) IN SCIENCE AND MATHEMATICS in the Pontypridd Junior Technical Schools (Building)—The Director of Education, County Hall, Cardiff.

## SCIENTIFIC AND INDUSTRIAL RESEARCH.—IV

WE have now considered the questions which arise in regard to personnel, whether of its quality or of the tactics by which the best use can be made of the men and women trained for scientific and industrial research. We have seen that some regard must be paid to our needs, not only in respect of quality but also of the numbers of such workers. Any serious discrepancy between the output of such trained men and women from the universities and technical colleges and the demand of the nation for their services must have serious consequences, either by impeding the immediate execution of our research programmes, for example, or by discouraging men and women of the highest ability from entering on such careers.

No attempt can be made to estimate our quantitative requirements in regard to research workers and other classes of scientific workers without some consideration of the actual programmes of research at which they will be required to work or of the openings for their services in other fields. This, accordingly, is the next step to be taken in approaching the consideration of the actual organization to be set up for the planning and execution of our research programme. If, as the Nuffield College statement suggests, the vital question at present is how much Great Britain must spend at once on scientific and industrial research in order to reap the fullest possible advantage of her resources of man-power and productive capacity, the answer can only be given after consideration of specific needs and projects, and as a result of the elaboration of concrete plans of development in a great number of particular fields. Moreover, it is only as such specific plans take shape that we can see at what points development is uneven, what gaps require filling and what weaknesses should be strengthened.

The Nuffield College statement is not concerned with such specific plans, and largely excludes from its survey the needs of agriculture, health and other fields which make a special call on trained biologists. None the less its paragraph on the claims of biological science is clear warning that there must be some consideration of the relations of the particular programmes and the demands they involve in order that our available resources may be distributed to the best advantage, and our research effort not badly thrown out of balance. It may well be doubted whether hitherto biological studies have attracted anything like a high enough proportion of the best scientific minds, and if that is so, the position is one that can only be remedied over a period of years. Advances in the biological sciences are fundamental for progress in agriculture, horticulture, forestry, food preservation, fisheries, conservation of water supplies, health education, and for the solution of other pressing world problems. They are vital for the future of tropical countries, for the mastery of soil erosion and for the repair of much of the devastation wrought by man upon his environment during the years of wasteful exploitation of natural resources.

It was suggested by the Parliamentary and Scientific Committee in its report on "Scientific Research and the Universities" that the future impact of biological advances in agriculture, medicine, nutrition and sociology may be of the same order of importance as that of physics and chemistry in the past fifty years. The demand for biologists in the post-war world is bound to be very large, and Great Britain is not well equipped to supply it. Moreover, the Nuffield College statement further points out, the experience of the War has shown that the trained biologist is a highly adaptable person, capable of making most valuable contributions to the solutions of problems quite outside his special field of study. That has a bearing on the position of biological science in the content of our general plan of education, and there are other considerations which should induce us to give general biology a higher place in the curriculum. At least it can be said that the place of biology in reconstruction demands a special survey, with an expansion of research and the formation of further chairs at the universities in such related subjects as genetics, ecology, biochemistry, and veterinary science.

Closely related is the question of social biology. The contribution which biology might make to the ordering of a new world, not merely as a corrective to mechanized planning but also as a guide to a true way of life, to the establishment both of greater control over our environment and over ourselves has been well emphasized by Sir Walter Langdon-Brown (*Nature*, 152, 166; 1943) as well as by Dr. K. E. Barlow in "The Discipline of Peace". That contribution may be as vital to the wise use of our natural resources as to the development of the appropriate organization of our affairs, both in regard to the conduct of scientific and industrial research, and the better ordering of international relations. Discussions such as those proceeding on world security at Dumbarton Oaks need to be examined, and their proposals require objective criticism by those trained in the scientific method so that disciplined and well-informed judgments based on values and not on extravagant and prejudiced opinion are reached.

Here we touch on a further field where our research effort in the past has been inadequate and where our technique is yet only being developed, because the limitations of the scientific method in situations involving judgments of value have not always been fully recognized. In his admirable little survey of the British universities in 1930, Sir Charles Grant Robertson urged that the advancement of knowledge could not without grave danger be limited to research in the physical sciences. In a revised edition of that book, which has just appeared, his argument is reinforced by all the experience of the past fifteen years, and he affirms his conviction that the only knowledge worth advancing is 'related knowledge'—knowledge of which the affiliations to, and contacts with, all other forms of knowledge are recognized and the total sum of which is purposively related to the ends of a civilized society seeking to fulfil a spiritual interpretation of life.

Sir Charles Robertson's plea is essentially that the universities can make themselves the central arsenals of a true humanism, but this question of social and economic research goes further and has a close bearing on many of the material problems with which we are confronted. The Nuffield College statement, in a passing glance at research in relation to social and economic policy, indicates how fruitful such research could be even from the point of view of securing more effective use of the results achieved by advances in industrial research in the physical field. Indeed the determination of the best form of structure, both government and non-government, for bringing about a co-ordinated study of economic and technical problems so that the machinery devised for shaping general economic policy will effectively relate the needs of consumers to the real potentialities of the productive system, in respect of type of product, quality and price, in the light of impartial scientific evidence drawn from both fields of research, is pre-eminently a matter for the consideration of Nuffield College.

The whole trend of the recent report "Government and Industry: A Framework for the Future" issued by a Fabian research group encourages the hope of a more impartial and objective approach to such problems. The importance of this field and the wide scope for impartial inquiry it offers can well be seen in the annual report of the National Institute of Economic and Social Research and especially in the recently published account of its publications and programmes. The need for a more equable distribution of our research effort between the social and biological and the physical sciences, whether at the fundamental level in the universities or in the attack on the practical problems of production and administration, is well illustrated in an article on the "War-time Social Survey" contributed by its director, Mr. Louis Moss, to *Public Administration* of October-December 1943. Mr. Moss pointed out that social research assists the administrator by enabling him to take the major relevant social facts into consideration in framing his policy, to measure the extent to which his policy has been successful after it has been put into operation, and to decide what changes, if any, are necessary to ensure its success; he also indicates five main spheres in which the Social Survey could be of assistance to Government departments in the post-war period.

The significance of the Social Survey's studies of food and clothing habits, and particularly the improvement of sampling methods, and the bearing of such studies on cost-of-living indexes and inquiries are obvious. Similarly, the work already done in checking the effectiveness of the educational publicity of the Ministry of Health and in exploring resistance to such schemes as child immunization against diphtheria is a promising aid to prophylactic measures which could raise the general standard of health. The value of the techniques by which the Survey has during the War rapidly secured a fairly good picture of the nutritional situation of the nation as a whole, or of particular groups, is also clear. Social research can also make an effective contribution to the removal of obstacles to a complete productive effort and thus assist in the full use of our skilled

man-power which is likely to be no less important after, than during, the War, and finally it should equally assist in eliminating many of the errors in housing and building policy which have arisen through imperfect contact of the administrator and expert with public needs.

This function of social research is, of course, essentially the elaboration of an effective liaison system, thus enhancing the adaptability of our social and industrial organization—the vital problem in elaborating an effective organization, as Dr. J. T. MacCurdy insists. Without going into further detail, it should be emphasized that not only are research workers required in these broad fields of biology and economics and social science but until, in some degree, the programmes of research are formulated, we cannot forecast approximately the numbers of workers in these fields which the universities are expected to provide. Furthermore, as is brought out to some extent in the statement "A Post-War Policy for Science", issued by the Association of Scientific Workers, these programmes themselves at times impinge on programmes for the development of natural resources and may determine their expansion or contraction. Nor can we well consider the re-orientation of our research effort until the broad programmes of work proposed in the different fields are seen in sufficient detail for a true perspective to be obtained.

It must not be imagined, however, that it is only in the social and economic field that there are gaps in our research effort, or special reasons for expansion. Sir Ernest Simon, for example, has directed attention to the neglect of aeronautical engineering, and to the active intervention of the Ministry of Aircraft Production to found an effective school of aeronautical engineering research. Again it is only possible to assess the importance of such gaps when we obtain from the broad programmes a picture of the general position.

Some attempt has been made by the Association of Scientific Workers in the statement already mentioned to cover the ground, and a number of particular programmes has already been outlined, such as that of the British Coal Utilization Research Association, for a thorough scientific study of the fundamental properties of coal. Despite the stimulus of the proposals of the Hot Springs Conference no adequate programme of nutritional research or of agricultural research has yet been formulated. Some of the main specific topics in the latter field are indicated in the Association of Scientific Workers statement, while, as we have already seen, the former involves not merely biological research but also the co-operation of workers in social science.

Closely related to this last is the field of medical research, and it may well be expected that one consequence of a national service for health will be a fresh impetus to research on the elimination of conditions responsible for sickness absenteeism, accidents, industrial disease and low standards of health or physique. The man-power situation is also likely to increase the importance of such work, as is the general age-structure of the population. Apart from this there is the stimulus that is derived from the striking advances in chemotherapy during recent years and from the realization of the immense resources which science has given us for preventing and eliminating disease apart altogether from its treatment. Besides this, as Dr. Alan Gregg has suggested, increasing attention to the geography of disease and, as a natural corollary, to the study of the relation of climate to disease and health, is called for. The effect of differences of environment on genetically similar organisms, biophysics, and the application of genetics to the study of human disease and human physiology, as well as both chemotherapeutic and pharmacological research, are likewise fields where he considers development is needed and probable.

In deliberately directing attention to fields where research has been comparatively neglected, or where at least exceptional expansion is required, it is not suggested that other fields of research, either industrial or fundamental, should not figure prominently in our post-war programme. From the point of view of the national economy the main problems in some branches of manufacturing industry, in transport, and in communications may well be, as the Association of Scientific Workers suggests, concerned chiefly with effective planning and co-ordination in a policy of full employment and social welfare. In other branches of industry, progress is dependent on fundamental research on such questions as the mechanical and magnetic properties of metals, their corrosion and lubrication, the molecular physics and mechanics of rubber and plastics, including the various synthetic fibres, while the position of petroleum as a raw material is shifting the whole outlook of organic chemical industry, raising important economic as well as technical problems. Nor can our survey of programmes be limited to our own internal needs: we are already committed to large and to growing programmes of Colonial research, including industrial, agricultural, geological, fisheries, animal health, forestry and medical and social research, and topographical and geodetic surveys.

As we have already emphasized, if proper use is to be made of our available resources, both of man-power and materials, it is imperative that at an early stage there should be some overall view of the main objectives, as distinct from detailed or particular subjects in all the main fields of industrial and the chief branches of pure and applied science. Only so can be put together some rough estimate or global figure in terms either of men or financial or material cost. Until that has been done we are neither in a position to make the intelligent allocation of priorities of grants, of men and of materials, which in the early post-war years will be essential, or to see at what points there are gaps likely to delay progress, or obstacles to the prosecution of fundamental research for advancing the boundaries of knowledge on a broad front on which the ultimate success of any programme of research depends.

There can be no disguising the tremendous demands which this task of reviewing or co-ordinating the programmes of research in so many different fields will make. Scepticism as to the adequacy for such a

purpose of particular proposals as that of the London Chamber of Commerce in one of its recent reports should not induce a *non possumus* attitude. On the contrary, experience of what has in effect been achieved in the prosecution of the war effort should inspire a new attempt to improve on that organization, to adapt it where necessary, and, profiting by the mistakes of the past, to seek to deal with the research problems of the peace on lines retaining sufficient flexibility to avoid constricting the spirit of free inquiry, while ensuring that problems which are most urgent from the point of view of the public interest receive priority of effort and supplies; and that there is no neglect of important fields or problems vitally affecting public welfare, or the advance of either industry or of science because they are not sufficiently the concern of any particular body.

Finally, it must be remembered that from the point of view of scientific workers themselves some attempt to sum up the requirements of research from a national point of view and to indicate the broad fields to be intensively developed is equally important. First, it provides the universities with a rough basis on which to estimate the numbers of trained workers required both in total and in different branches of knowledge. Demands for workers in the natural sciences can be balanced with those for workers in the growing body of statistical, economic, sociological and psychological studies of no less importance to the community and to industry. But beyond this, it brings to research workers in any field a growing awareness of the relations of their problems to those of students in other fields. That consciousness, with the more intimate contact with research workers who are asking other questions and employing other methods, which should flow from the new and fuller integration of our research effort, should help to break down the isolation with which scientific workers have sometimes surrounded themselves in the past, and it should impart not merely a quickening sense of social or public service but also that fertilizing cross-current of ideas which always lies at the roots of creative thought and intellectual advance.

## A SURVEY OF THE U.S.S.R.

The U.S.S.R.

An Economic and Social Survey. By Dr. S. P. Turin. Pp. xiii+220. (London: Methuen and Co., Ltd., 1944.) 16*s*. net.

ENGLISH readers often find it difficult to obtain trustworthy information about the U.S.S.R. They suspect anything that looks like propaganda and much prefer a cold and clear-cut account that aims only at presenting the facts without bias one way or the other. For this reason much that has been written has lacked permanent value, and has probably had far less influence than its authors had hoped. On the other hand, the official statistics, which are good, are not easily accessible to the ordinary reader.

Dr. Turin's survey has the special value that it is based on official statistics, elucidated often by diagrams and presented objectively. He begins with an account of the geography and ethnography of the U.S.S.R.; then he discusses its regional structure, with which many readers will be unfamiliar. The centralization of production in the hands of the State has meant the welding of great areas into huge industrial units. The Moscow industrial region, or *oblast*, for example, has a radius of about 100–120 miles with Moscow as its centre, but every town, every village and every hamlet within it forms part of one big industrial concern. The importance of this particular *oblast* is that although it represents only about 1 per cent of the U.S.S.R. territory, it contains about 10 per cent of the total population and more than 25 per cent of the total industrial population.

Next follows an account of the industries themselves, beginning with agriculture. Before the Revolution, about 75 per cent of the population were engaged in agriculture; the 1939 census, however, showed only about 50 per cent so occupied. The figures are not quite clear, however, because in the summary table the workers on the State farms are apparently grouped with town workers, while those on the collective farms are given separately. The change from the older inefficient peasant system to more modern methods, and the great development of mechanization, enabled men to be released from the farms for the staffing of the new factories without any loss of food-producing power; there has, on the contrary, been a gain. The products, however, still remain in the same order of importance as before: grain still has the first place and livestock represents only about one quarter of the value of the output: relatively less than in 1913 and not much more in actual value.

The author recognizes the profound change in character of the collective farms since their inception, although the name has been retained throughout, and in an appendix he gives a clear translation of the rules set up by the central authority in 1935 and still valid. Of the cereals, wheat is the most important, and its output, which fell for many years after the Revolution, has risen since the second Five Year Plan began in 1933. The author does not, however, mention that in that year a new method of estimating yield of cereals was introduced which gives higher values than the old method; it is almost certainly a better method and its results are more likely to be trustworthy, but the change makes comparisons difficult. It is stated on p. 109 that the yields used to be over-estimated; but the evidence appears to point the other way. Rye comes next in importance, but its output has not expanded since 1913 although the population has grown. Oats have the third place, and these have increased to about the same extent as wheat, a result of the increased output of livestock products. The tables would have given a more faithful picture of the cereal position had they been continued beyond 1937. That was a magnificent season for cereals, and the yields in many places exceeded all records. As the author points out, 1930 was also an exceptionally good year for wheat, and the output jumped up to 35 per cent above its general level for the two years before and after: in 1937 the jump was even greater. I myself saw both these crops, and there was no doubt about their exceptional character.

Other branches of agriculture, especially technical, market garden and fodder crops, have developed

rather more than cereal growing, as usual when agriculture is being improved. The quantity of milk supplied to markets was in 1938 some $5\frac{1}{2}$ million tons, while in pre-Revolution days it had been only just over one million tons; the butter supplied to markets was formerly 120,000 tons per annum; in 1937 it rose to 185,000 tons. Meat production has also increased, and a packing industry has developed, this being the most convenient way of distributing the meat: nearly one thousand million cans are turned out annually, this being nearly six per head of population.

The timber industry has made less progress than agriculture, probably because of its inherent difficulties. There are in the U.S.S.R. (according to the "Great Soviet Encyclopædia") some 956 million hectares of forest, or 43 per cent of the total area, but much of this is in Siberia and transport of the timber is mostly by rail. Owing to clearances, increasing distances have to be covered: in 1933 the average distance of transport was 688 km., by 1937 it had become 1,055 km., and only 23 per cent of the timber could be transported by water. Added to these difficulties was what the author calls "the mistake of invading the industry with conscript labour, recruited from non-proletarian elements"—this, he says, has now been realized by the management of the industry as ill-advised.

The author has little to say about the industrial progress. An interesting chart on p. 122 compares the values of output from agriculture, industry and home industries in 1913 with those of later years, and shows the great fall by 1921 and the later recovery: by 1927 the values in millions of roubles were almost the same as in 1913. It is not stated whether the roubles had altered in value during that period, but the large prepónderance of agriculture is strikingly brought out. Unfortunately the chart ends there, and there is nothing to show whether agriculture has kept this great lead or not. Extensive data are given for outputs of the raw products of industry—oil, coal, ores and minerals—and there is an interesting account of gold-mining, which is still partly in private hands.

The book ends with some useful summary tables of imports and exports, some in tons and some in roubles, and a footnote directs attention to a change in the value of the rouble introduced on April 1, 1936, which is sometimes overlooked by writers and lecturers. Values prior to that date have to be multiplied by 4·38 in order to make them comparable with later values. The author does not say whether he has made this correction or whether it is left for the reader himself to do.

The book is so useful that a second edition may well be required. It would add greatly to its value if the author would give a little more explanatory information about the statistics and clearer indications of their sources. Two sets of official data are generally available in Great Britain relating to the U.S.S.R.: those in the official year-books and those in the reports presented to the party congresses, but they are not always strictly comparable one with the other. Periodically also other data appear in other official publications, but these again are not always comparable with the preceding, however good they may be in themselves. These differences in comparability are not always clearly indicated in the text, nor are the dates to which the figures refer always given. A striking chart on p. 104 shows the relative contributions of the individual farm products to the "total value of the whole yield of agricultural products". Grain and potatoes are grouped together; they would have been better separated: together they are said to represent 41 per cent of the total value of output. Live-stock account for 27 per cent but 'pasture' is listed separately at 16 per cent. 'Pasture', however, has no meaning apart from live-stock, and the reader is left wondering whether the 'pasture' has also been included in the 27 per cent for live-stock, in which case there is a certain amount of double counting, or whether its value has to be added to that of live-stock, in which case the total would come above that for grain and potatoes. But this cannot be right, as the official figure for the value of livestock products in 1937 was 25 per cent of the total output value. The text seems to indicate that the diagram refers to the collective farms: does it take account of the large number of live-stock owned by the peasants? (From the results of an inquiry reported in "Kolkhozy vo vtoroi Stalinskoi Piatiletke, 1940", it appears that the peasants in 1936 owned more animals than the collective farms.) It is not stated to what months the live-stock data refer, nor whether the figures for arable land include fallows intended for sowing but not yet sown. Fuller information would be particularly useful for the charts, which are otherwise very helpful. No dates are given for the population charts on pp. 11 and 13, though one apparently refers to an early census and the other to a later one.

It would be helpful also to give a little more information about the natural regions: English readers still think of European Russia, and the author indeed makes incidental references to it, but only indirectly can the reader estimate its size. It would be particularly helpful to agricultural students if the classification of the regions into tundra, marsh, forest, steppe, desert, etc., given only in a footnote on p. 4, could be expanded: that is the one used mostly in Great Britain. Finally, we should be grateful for a table showing the land utilization in the various regions of the U.S.S.R. The book is so good that one can safely anticipate it will have a long and useful life, and anything that will add to its value can be welcomed. E. J. Russell.

# A NEW DETERMINATIVE TABLE FOR ORGANIC COMPOUNDS

**The Optical Properties of Organic Compounds**
By Alexander N. Winchell. Pp. xiii+342. (Madison, Wis.: University of Wisconsin Press, 1943.) 5 dollars.

The value of the polarizing microscope in identifying and characterizing minerals is well known, but its application to organic crystals is not yet by any means general. The customary description of a new compound includes a precise statement of its melting point, boiling point and other physical properties; but when it comes to crystalline form the description all too frequently lapses into the vagueness of white needles, orange prisms or colourless plates. A more careful description of superficial appearance is perhaps considered unnecessary because crystal habit is notoriously dependent upon environment during growth, and may vary from one preparation to another. If reasonably well developed crystal specimens are available, resort to the goniometer will provide data which are definitely char-

acteristic of the compound. Very often, however, such well-developed specimens can only be obtained with considerable difficulty, and the material is more usually in the form of minute, even microscopic crystals or fragments of crystals. It is perhaps not generally realized that on such unpromising material the polarizing microscope can provide accurate measurements, not of one but usually of several distinct physical constants which, taken together, provide an exceedingly reliable means of characterizing the compound.

The optical properties most useful for this purpose are the refractive indexes, usually three in number for compounds of low symmetry. The aim of the work before us has been to collect the crystallographic and optical properties of all organic compounds of which the indexes of refraction have been measured, up to and including the year 1940. The description of each compound gives name, formula, crystal data, including habit and cleavage, with requent diagrams (no structural data are given, only axial ratios), density, melting point and a full and careful description of the optical constants. One difficulty which must be faced by the compiler of any work of this kind is in dealing with imperfectly determined data, as arises, for example, when crystals are studied in one position only (usually on the largest face, or cleavage surface). Indexes of refraction thus determined are not necessarily the true principal indexes, and in the present work all such cases have been carefully distinguished by listing such indexes as $N_1$ and $N_2$ to distinguish them from the true values of the principal indexes, $N_g$ and $N_p$. Such careful and critical treatment of the data by one who is a recognized authority on the subject gives a high value to the present work.

The arrangement of the systematic section, which includes more than a thousand organic compounds, follows that of the fourth edition of Beilstein's "Handbuch der Organischen Chemie", with slight modifications to bring certain isomorphous salts together. This is followed by a determinative table, occupying about seventy pages, in which substances are arranged in order of increasing index of refraction (the index for the ordinary ray, $N_o$, or the intermediate ('mean') index, $N_m$, is used for anisotropic substances and the other indexes are also given). This information is then summarized in a very useful diagram on which all the compounds are plotted, refringence ($N$, $N_o$ or $N_m$) along one axis, and positive or negative birefringence along the other. By means of this diagram and its key, any of the compounds listed can be very quickly identified solely by its refractive indexes.

The appearance of this work brings to mind two other systems, already in progress, which aim at the identification of a substance by means of its crystalline properties. In the Barker Index at Oxford, substances are classified according to their characteristic interfacial angles, and rules are provided to ensure that no ambiguity shall arise in the choice of the classification angles. It is understood that considerable progress has been made in the compilation of this index, and trials have shown that positive identifications can be made with considerable speed[1].

Finally, there is the Index of X-ray Diffraction Data prepared by the American Society for Testing Materials[2,3], which aims at rapidly identifying any substance that will give a powder photograph. This method is undoubtedly the most universal in its application, as visible single crystals of the material are unnecessary. But X-ray apparatus, however, is still a rarity in many chemical laboratories.

These various methods for the rapid identification of substances will undoubtedly become of increasing importance in the future, as the necessary data are accumulated and become classified. The factor which severely limits the usefulness of all these methods at present is the comparatively small amount of accurately ascertained data in comparison with the vast number of known chemical substances. Further progress on any of these projects will call for carefully planned co-operative work on a very large scale. Some kind of conference is needed to decide on the best methods and to organize the work.

Even if the average chemical laboratory does not possess a goniometer or an X-ray apparatus, it should at least have a good polarizing microscope, for optical measurements on crystals have an importance far exceeding the rather utilitarian aspect of mere identification. In elucidating unknown structures, for example, they played a great part in Bernal's early work on the sterols[4]. In the main day-to-day work of the chemical laboratory the microscope, if competently used, can effect a great saving of time and labour[5]. Winchell's book should therefore make a wide appeal to those who have become familiar with the uses of this valuable instrument. J. MONTEATH ROBERTSON.

# BACKGROUND OF ART AND SCIENCE

## Art and Scientific Thought

Historical Studies towards a Modern Revision of their Antagonism. By Martin Johnson. Pp. viii+192+16 plates. (London: Faber and Faber, Ltd., 1944.) 16*s*. net.

IT is impossible to mix with people these days without continuously meeting the question of values. "Why do we do this, and why do we do that?" Not so much *how* as *why*. Otherwise expressed, there is a tendency to show less interest in systems of law than in ends to be attained, an outlook essentially teleological in character. Historians, including those of the arts, will breathe freely in such an atmosphere, and scientific men (or at least some of them) would experience a certain awareness that experimental knowledge cannot indefinitely rid itself of responsibility for its discoveries, for good or for ill. Dispositions something like these have clearly been at work in Dr. Martin Johnson's mind, and the remarkable book before us is the result.

To begin at the beginning, Mr. Walter de la Mare writes as charming a foreword as only he can do. Discussing poetry, he says that "Mere endeavour will neither achieve its creation nor win the secret of its power and beauty". But immediately before this he remarks that "poetry . . . is essentially different" [from science]. The implication is perhaps scarcely happy. The supreme accomplishments of science are —of their kind—pure art, and those responsible for

them are, like poets, born not made. It is true, of course, that works of art endure, whereas even the best of scientific theories do not. The latter are for ever yielding place to less imperfect successors. But for all that, "power and beauty" are shared by art and science alike, in mutual reverence.

Dr. Martin Johnson himself starts with a series of essays, dealing with those features of the arts and sciences which show marked resemblances and contrasts. He traces the function of pattern, structure and form, and finds that, without metaphysical complications, the paramount need is for communication. To a work of art there is obviously an infinity of emotional patterns registered by different observers, whereas all mental judgments of a scientific theory tend necessarily to identity.

We are next presented with a number of examples of imaginative stimulus. Perhaps these are the most revealing pages of the book, and indeed they are entrancing. Beethoven's last years, and his music, are pictured with sensibility and yet with restraint. In a few sentences the author casts upon this scene of distress what Whitehead meant when he defined religion as "what the individual does with his own solitariness". It is all too likely that the great musician could but point others to the skies, chained and bound to earth as he was himself.

From such quests of the imaginative, Dr. Martin Johnson turns squarely to apply the historical method in his descriptions of Persian, Arab, Greek, Moslem and Chinese investigations relative to mathematics and the design of scientific instruments. It is well done, if a trifle heavy compared with the rest. These chapters end with an able discussion of symbolism and its place in some future conciliation between science, religion and art. Of course, this theme has been attempted before. One has only to recollect such diverse names as Otto, Streeter, Collingwood, to realize how 'pontifical' (in the correct sense of the word) an approach this is. Seldom can synthesis have been more effective.

The last five chapters are devoted to Leonardo da Vinci. Considering the weight of scholarship which has already descended upon the elucidation of this remarkable personality, this new contribution is fresh in outlook and distinguished in presentation. Leonardo had no love for pure mathematics, and even less for metaphysics. His experimental genius derives fundamentally from Archimedes, for whose works, by the way, he sought long and patiently, against enormous odds. There is little doubt that, consummate artist as he was, he became ever more and more engrossed in scientific work, which led him on to a type of extreme veneration for natural law.

In general, the historical point of view is suited to the aim of this volume; its constant use, however, tends to exclude completely certain modern aspects of the relations between the arts and sciences which are much to the point. Maybe the future will provide opportunities for ventilating them; in any event, such a background as we have here is a necessary pre-condition for their appreciation.

Incidentally, there are a few odd little mannerisms; readers' memories may be short, but it seems needless to repeat the dates of the Chou dynasty three times in six pages. The index is strangely capricious: sometimes proper names are entered, sometimes not, without any apparent reason. Occasionally the missing reference is much more interesting than the one which is listed.

Finally, this is certainly the moment to discern—and perhaps even the place to rejoice in—the author's abundant charity, which seeketh not her own [and] is not easily provoked. Dr. Martin Johnson has produced something of great price, and of engaging modesty; of that wisdom, in fact, which stoops to conquer. F. IAN G. RAWLINS.

# PHILOSOPHY AND PHYSICS

**Fact and Fiction in Modern Science**
By Henry V. Gill. Pp. vi+194. (Dublin: M. H. Gill and Son, Ltd., 1943.) 8*s*. 6*d*.

THIS book is substantially a reprint of essays which have appeared at different times in various journals. The author has the advantage of a more profound knowledge of philosophy than most popular writers on science, and his comments are more sober and orthodox than might perhaps be anticipated from the somewhat flamboyant title. The scope is sufficiently indicated by chapter-headings such as "The Nature of Scientific Knowledge", "From Physics to Philosophy", "Logic and Modern Science", and "Determinism, Uncertainty, and Free Will".

An interesting suggestion (p. 24) is that "the philosophy of Eddington would seem to approximate to that of the scholastics". To justify this affiliation, one may start from Eddington's affirmations that "all that physical science reveals to us in the external world is group-structure" and "Physical Knowledge is structural knowledge". But if we try to develop the Eddingtonian philosophy consistently beyond the point to which Eddington himself has carried it, we are led to inquire what (if anything) is this structure the structure *of*? What would, so to speak, be left behind if all structure could be imagined as annihilated? Clearly it cannot be ordinary matter, for ordinary matter even in its most elemental form as electrons, protons, etc., has qualities which must be included in the category of structure: the ultimate residuum which is wholly devoid of structure must be a limiting conception, a pure potentiality, something not capable of existing alone; and surely this is nothing other than the *materia prima* of the scholastics, Eddington's 'structure' being equivalent to the scholastic 'form'.

The author makes a curious slip when he says (p. 178), "To *prove* to one who denies it that two and two could not in any condition of things make five is beyond the power of any philosopher". Although this particular problem does not figure explicitly in Whitehead and Russell's "Principia Mathematica", a demonstration could undoubtedly be provided by the methods of that work.

The treatment is, generally speaking, well informed on the purely scientific side, the only noteworthy exception being that the author misconceives Heisenberg's uncertainty principle. In one place (p. 111, last three lines), he seems to be under the impression that the uncertainty is merely a consequence of the inadequacy of experimental methods now available, instead of being, as it actually is, an uncertainty *in principle*. Elsewhere (p. 24, lines 9–11) he seems to confuse it with the lack of detailed information about individuals which is characteristic of all statistical systems. But these are minor blemishes in a readable and instructive book. E. T. WHITTAKER.

# 'D.D.T.': A NEW INSECTICIDE

By PROF. J. W. MUNRO
Imperial College of Science and Technology

A STATEMENT by Government to the public Press on recent developments in the application of the insecticidal substance known as 'D.D.T.' and the extensive publicity given in the American Press and technical journals to this insecticide have directed attention to a field of work in applied entomology which in peace-time is almost unknown except to the specialists.

With the outbreak of war, and especially when Japan entered the War, the need to protect growing crops and stores of food from insect attack, and above all the need to protect the Fighting Services from insect-borne diseases, created an unprecedented demand for insecticides. In the face of that enormously increased demand, by the mere entry of Japan into the War, supplies of the important insecticide pyrethrum from that country to the United States were cut off. Worse still, with the loss of Malaya the main source of rotenone derived from *Derris elliptica*, a second important insecticide, was lost. The chief, almost the only important, source of pyrethrum left to the Allies was Kenya Colony, but its production was unequal to the war demand. A limited supply of rotenone, inferior as an insecticide to that derived from Derris, was available in South America from the plant Lonchocarpus, but again the supply was unequal to the demand. It was in these circumstances, when an urgent and active search for substitutes for pyrethrum and for rotenone was being made, that attention was turned to 'D.D.T.'

'D.D.T.' is a term coined to designate briefly the substance dichloro-diphenyl-trichloroethane, and the term 'pure D.D.T.' designates *para-para*-dichloro-diphenyl-trichloroethane, which is the most active isomer. In the trade, an insecticide containing 'D.D.T.' as the active ingredient was marketed in the United States as 'Gesarol' and in Great Britain as 'Neocid'. Neither the discovery of the substance itself nor its use as an insecticide is new; but, under the necessity of finding substitutes or near substitutes for pyrethrum and for rotenone as insecticides, new applications or uses for 'D.D.T.' have been developed both in Britain and in the United States.

'D.D.T.' has proved an unusually effective insecticide with more uses than any other single substance so far available, and has already more than justified the intensive work done on its 'development'. For example, it has been used with signal success in Italy—notably in the control of a typhus outbreak in Naples when, in January 1944, 1,300,000 civilians were dusted with 'D.D.T.' powder and within three weeks the outbreak was completely under control. This is the first occasion in medical science when a typhus outbreak has been arrested in mid-winter.

The significance of 'D.D.T.' as an insecticide can best be assessed by comparing it with other insecticides used. Briefly, these are pyrethrum, derived from the flowers of *Chrysanthemum cinerariifolium*; rotenone, derived from the roots of certain leguminous plants, of which species of Derris and Lonchocarpus are the more important; and synthetic insecticides such as the organic thiocyantes and *iso*-butyl-undecylenamide.

The outstanding feature of pyrethrum is its rapid action, technically described as 'quick knockdown'. Its defects are that, as ordinarily applied as a 'pyrethrum-kerosene' spray, it is not persistent, and that to some skins it is irritant, and susceptibility to irritation increases under continued exposure.

Rotenone lacks the rapidity of action of pyrethrum, is not suited for application in kerosene but is more effective as a dust. In this form it is more persistent than pyrethrum and does not cause skin irritation.

The thiocyanates and *iso*-butyl-undecylenamide more nearly approach rotenone than pyrethrum in their insecticidal action—they lack the 'knockdown' action; they are more toxic to man and animals, and the thiocyanates have a persistent unpleasant odour which quite seriously limits their use.

'D.D.T.', while lacking the rapid action of pyrethrum, has all the good insecticidal qualities of rotenone and the synthetics. In pure form it is practically odourless and it is remarkably persistent. When sprayed on walls at a suitable concentration, 'D.D.T.' kills any fly alighting on them up to a period of three weeks; a bed sprayed with 'D.D.T.' is fatal to bed-bugs for three hundred days, and clothing dusted with it is safe from lice for a month even after several launderings.

In agricultural and in veterinary pest control, as the tests conducted by the U.S. Bureau of Entomology and Plant Quarantine[1] show, 'D.D.T.' also shows high promise.

The truly astonishing rate at which 'D.D.T.' has been 'put through its paces' by the biologists, chemists and malariologists both in the laboratory and in the field, and the extensive demonstration of its value as a general-purpose insecticide, has led in some quarters to the assumption that 'D.D.T.' will rapidly replace all the older insecticides, and even to the assumption that much research as, for example, on the methods of testing insecticides, on the relative merits of aerosols and sprays and on the physical and physiological modes of action of insecticides, is no longer necessary. Such assumptions are unwarranted. While on the practical side 'D.D.T.' has provided a solution of our difficulties far beyond expectation, on the scientific side it has raised many problems and difficulties which, while they cannot be fully tackled in war-time, must yet be tackled before the full potentiality of 'D.D.T.' and—this is important—of the methods of using it can be realized. This demonstration of our ignorance of many factors affecting the full use of 'D.D.T.' is bound to react on the development of other insecticides. 'D.D.T.' is not the successful rival ousting all other insecticides from the field. It is a challenge to the chemists and the entomologists to develop these other insecticides by applying to them the same exhaustive and critical study that has been given under pressure of war to 'D.D.T.' Pyrethrum, for example, is still essential as an ingredient—perhaps with 'D.D.T.'—of sprays designed for the rapid destruction of mosquitoes. When peace returns, the factor of costs both in production and in application will once again become important and rival insecticides will enter the field—one called '666' has already done so[2].

It should be borne in mind that an important factor in the success of 'D.D.T.' lies in its trial and use on a lavish—by pre-war standards on an extravagant—scale, and until the War ends it will be difficult to see 'D.D.T.' and its competitors in proper perspective.

In looking forward to that time, one may express the hope that the herculean efforts now being made to destroy insect vectors of disease and depredators

of our crops and food stores will not be abandoned, as efforts on a lesser scale were abandoned in 1919. During the War of 1914–18, the most widely used specific against lice was a rather crude mixture called 'N.C.I. powder'. It is interesting to note that, according to Prof. P. A. Buxton's monograph published in 1939[3], it was still on the active list.

The neglect of applied entomology except in times of crisis has cost us dearly enough; in this present War, but for the efforts of a group of administrators and men of science working in close concert, it might have cost us even more. In the United States, Government departments, university and research institutions and individual workers themselves have described the magnificent effort they have made in this field. In Great Britain, official reticence, if not secrecy, has delayed until now any reference to the equally great effort made by workers in many fields, administrative and technical; industrial and scientific. The co-ordination of that effort and the startlingly successful development of 'D.D.T.' was possible only under able and distinguished leadership, both in the military and in the civil branches, and it is to be hoped that in due course that leadership may be acknowledged.

# THE VISUAL EDUCATION CENTRE, EXETER

By G. PATRICK MEREDITH

University College of the South-West, Exeter

VISUAL education starts with certain raw material in the form of items of organized knowledge (usually in verbal form); converts it into *visual matter* (photograph, diagram, etc.); presents it through some *visual medium* (wall-mount, ciné-projector, etc.); and usually combines it with oral teaching—all to help the learner to learn more efficiently than by the latter alone. At every stage problems arise. The field is wide and there are many workers in it. At the Visual Education Centre at Exeter we are endeavouring to find solutions to these problems; at its recent research conference its possibilities of usefulness, both as a research institution and as a forum, were demonstrated. (The Museum has a very important function in visual education. I have made no attempt to deal with this as it is beyond the scope of my title.)

The problems fall naturally into three main groups, concerned with visual *matter*, visual *media* and visual *methods*, respectively. The distinction between matter and media is all-important. The matter may be pictures, diagrams, pictograms, maps, symbolic charts, mathematical graphs, etc. Any of these may be presented through any of the visual media, namely, wall-mount or text-book illustration, episcope projection, diascope projection through lantern slide or film-strip, and lastly ciné-projection (silent or sound). Moving matter (ciné-film), microscopic matter and stereoscopic matter are restricted, of course, to special forms of presentation.

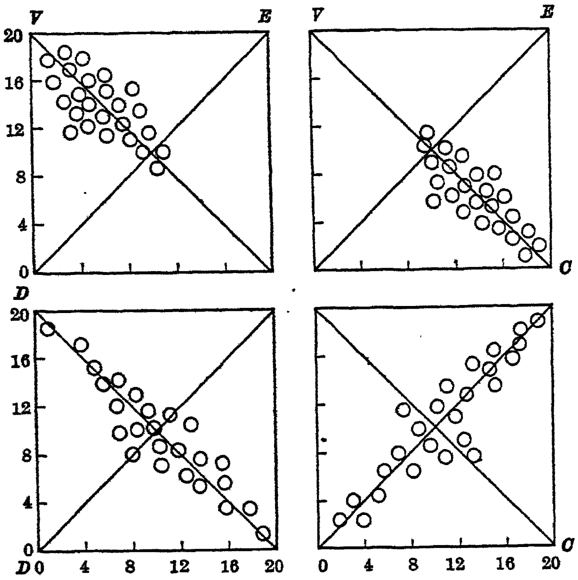
Extravagant claims for some particular medium are often made by enthusiasts who forget that we cannot get more educational value out of any material than was put into it; hence the need for the closest collaboration between film producers and educationists. Thus our major problems are with the design and supply of visual matter. These are fundamental. Next comes a series of practical problems concerning the design and supply of apparatus; training in manipulation; maintenance and repair of equipment; finance, etc. Thirdly, the use of these media has to be integrated into the work of the teacher and into the curriculum as a whole. All these problems require systematic investigation.

## Origin of the Centre

The stages by which the Visual Education Centre came into existence were briefly as follows. In 1940 I began, as a lecturer in the Education Department of the University College of the South-West, to specialize in the study of visual aids; the experience of a dozen years of science teaching had convinced me of their value. Visual education was incorporated into the diploma course and I gave students a training both in the handling of visual media and in the design of visual matter. At the same time I became secretary of the Film Council of the South-West, a recently established committee for the encouragement of the cinematograph for both instruction and entertainment. The Council represents the local education authorities, the University College, the schools, the cinema trade, the Ministry of Information and the British Film Institute. The latter, together with the local education authorities and local subscriptions, finance the Film Council. The secretaryship, at first voluntary, came to be accepted as College work, thanks to the goodwill and foresight of Principal John Murray, and of Prof. S. H. Watkins of the Education Department. Other work had to be dropped and funds raised to appoint a substitute; the director of the British Film Institute was instrumental in obtaining grants from industrial concerns, and the position was consolidated by the establishment of a lectureship in visual education. Equipment was purchased, clerical and technical assistance provided, temporary huts appropriated, and last year a research assistant, Dr. Renée Marcousé (now assistant lecturer), was appointed.

The Centre is fully occupied in training students, providing teachers' courses, supplying advice and information, providing film shows and other visual demonstrations both in the College and outside, for schools, for the Forces, for civil defence and other national services, for adult education and so on. It now issues its own bulletin, approximately quarterly. It maintains a very wide circle of contacts in all branches of visual education. Recently problems of aeronautics and industry have been insistently raised, and the setting up of an industrial section is contemplated. All along, the Centre has paid its way by grants raised *ad hoc*, now running well into four figures.

One of the Film Council's earliest achievements was the establishment of a regional film library. Dartington Hall generously provided housing and personnel. The Ministry of Information substantially aided the new library by choosing this as a regional distributing centre for the whole south-west region. Much valuable experience has been gained in this way, and the five counties have been kept supplied with non-theatrical 16-mm. films for the last three years.



ASSESSMENT OF VISUAL MATERIAL BY TEST-SCORE ANALYSIS

The small circles represent individual test-questions. In any actual distribution they are numbered, and coloured according to type. Each has two co-ordinates *C* and *V*, being the number of correct responses to the question given by the Control group and the Visual group respectively. (There were approximately twenty children in each group.)

The four distributions shown are some of the extreme distributions theoretically possible: 1 indicates a test favouring the visual group almost exclusively; 2, Control group favoured; 3, approximately half the questions favour the Visual and half the Control group; 4, few questions discriminate between the two groups.

Obviously various statistical coefficients could be calculated from the data, but the main interest lies in the indications which the method provides of the detailed 'educational yield' of a particular piece of visual teaching.

*DE* may be called the 'axis of difficulty', and *VC* the 'visual-verbal axis'.

## An Experimental Inquiry

Research, both experimental and theoretical, is the most important contribution a university centre can make. An investigation into visual teaching techniques has recently been completed in Exeter. The statistics are now being analysed, and a full report will be issued in due course. Owing to the inherent variability and multiplicity of the factors involved, the utmost caution is needed in interpreting the results of any educational experiment. A difference may be statistically significant, but the qualitative significance is often a matter of conjecture. A certain percentage difference ($\pm$ p.e.) between the average test-scores of two groups tells us very little. It is conceivable for two groups to have equal average scores and yet to have answered correctly two entirely different selections of questions. In the Exeter research particular attention was paid to the content and structure of the topics on one hand, and to the distribution of correct answers among the various test-questions on the other hand. The accompanying diagrams give four of the various theoretically possible distributions, with their interpretations. The actual distributions, still being worked out, tend to be mixed in type, as would be expected.

The research seeks detailed information of two kinds. The first is an objective educational assessment of a particular 'graphic' (to borrow a useful term introduced by Lieut.-Commander Rawnsley, covering all forms of visual material) whether film, set of photographs, etc., or combination of these. Such information is essential if visual production is ever to work by methods other than rule-of-thumb. The second is a descriptive account of the practical problems which arise in the classroom in handling 'graphics', and the solutions adopted by a number of different teachers. A comparatively small-scale experiment, closely recorded, may yield more valuable information than a much larger experiment which swamps the desired information in arrays of averages. Four schools were used. There were two groups in each, a 'visual' and a 'control'. The teachers were supplied with detailed notes of the topics and with visual materials. Initial, final and delayed tests were given. They were objective 'new-type' tests. Four different topics were chosen and each was tried out in all four schools, but the visual method was slightly different in each case. The four methods were: film alone, static pictures alone, film plus static, and segmented film plus static. (The theory of 'segments' will be given presently.) The test-questions were sub-divided under four headings according as they dealt with problems, observations (raw facts), representations (grouped facts, that is, laws) or inferences (explanations and theories). The dots representing each question in the analysis charts are coloured according to these four headings. The distribution then shows at a glance whether any one *type* of question is favoured by the visual or by the verbal method. This technique lends itself to considerable development, and promises to remove much of the subjectivity from judgments on educational materials and methods. Thus the research as a whole was not concerned with verifying any particular hypothesis but with creating techniques and obtaining valuable information.

Films often contain material which is essentially static. Such material is better presented in static form, the film medium being reserved for essentially kinetic aspects of the topic. The theory of 'segments' is that phases of growth, change, motion, etc., should be presented in short film-segments of, say, 1–3 minutes duration, for detailed study and for integration with static 'graphics'.

## Discussion of Results

The idea of research conferences is a sound one in a field where variation and multiple causation are the order of the day. The suspicion of statistics *per se* is a healthy one, but statistics submitted to a competent body of critics may yield very useful interpretations. A conference was held at Exeter during July 1 and 2 with personnel from the Board of Education, the local education authorities, the museums, the British Film Institute, the participating schools, Film Centre, Shell Film Unit, Common Ground, Ltd., Dartington Hall Film Unit, the Film Council of the South-West and the University College of the South-West. In the opening session the plan of the research was described and the "Exeter technique of visual assessment" explained by myself with coloured charts. Dr. Marcousé then gave an account of her systematic observations of the

teaching procedure and of the overt responses of the children to the visual material. (In the full report this will be given in detail.)

Next came the teachers. All four schools had shown a most gratifying willingness to co-operate. Perhaps the most interesting feature of their testimony was the unlooked-for result that, quite apart from the stimulus to the children, the use of these visual techniques had a distinctly stimulating effect on the teachers. The extremely cordial relationship between the teachers, the Visual Education Centre staff and the director of education, Mr. G. A. Tue, was the *sine qua non* of the whole research. The four Exeter schools taking part were the two Episcopal Senior and the two Ladysmith Senior schools.

The lesson notes, tests and visual materials were all on view. The latter consisted of four films and still material consisting of large photographs of high quality, well-mounted, bearing full captions, and covering the four topics. Other material was also demonstrated.

Discussion took place on classroom techniques, on the use of museum material and on the planning of educational films. Miss Grayson (of the British Film Institute) stressed the need for co-ordination. The problem of making museum resources available for the schools was discussed. Mr. Neilson Baxter (Shell Film Unit) pointed to the valuable experience gained by many ciné-technicians in the production of instructional films during the War. Mr. Anstey (Film Centre) urged the setting up of a Government films department. The present author pointed out that if producers would plan educational films in series, each series following a characteristic treatment, a prototype film for each series could be made and tried out by the Exeter technique. The evidence so obtained would provide guidance for the rest of the series. The conference was summed up by Mr. K. de B. Codrington (Victoria and Albert Museum), who stressed the simple common elements which run through all good teaching and the need for using each type of visual material for the purpose to which it is most suited.

### General Conclusions

Whatever researches are made on problems of media and methods, the fundamental problems are those of visual matter. Any visual production rests on a whole series of assumptions, conventions and decisions. No amount of technical or æsthetic virtuosity can compensate for a failure to come to terms with the philosophy of curriculum-building or the psychology of the child. One important factor often neglected is the contribution of intellectua security to emotional stability. Our existing curricula present children with an anarchic sequence of incommensurable and unintegrated approaches to knowledge. If visual education neglects its fundamentals, it may easily perpetuate this state of affairs. Theoretical research at the Visual Education Centre is therefore concerned with the bearing of three normative disciplines on visual production, namely, logic, semantics and statistical theory. Visual productions must be consistent, they must present their meaning clearly, and they must take account of the variability which all objects display. This is a long story, to be presented in a larger publication, together with an account of its bearing on the curriculum as a whole, and the significance of these new developments in relation to the teacher's function and to national (and international) educational needs.

## MATHEMATICS FOR PHYSICISTS

"MATHEMATICAL teaching," said Klein, "is a function of two variables, the subject and the pupil." In other words, it is necessary to vary the presentation of the subject to suit minds of different types. Nineteenth-century physicists, such as Kelvin and Maxwell, started as mathematicians, and many of the contemporary mathematicians relied upon physical intuition, so at that time a common course of training was possible. The interests of the two parties have now diverged. The pure mathematicians have recognized that intuition may be successful for a long time, and yet lead in the end to a terrible blunder. They now keep to the straight and narrow path of rigorous logic. For example, they do not, like Fourier, assert that any function whatever can be expanded in an infinite series of harmonic terms, but occupy themselves with the difficult task of formulating the precise conditions necessary and sufficient for this expansion.

On the other hand, experimental physicists regard mathematics as a tool, to be used whenever it is convenient to supplement the results of experiment, or as a language in which these results can be concisely expressed. To them Fourier's theorem is merely the mathematical form of a general physical principle, firmly established by experience. Why should they worry about possible exceptions which may never happen? They prefer vigour to mathematical rigour, which seems to them as devoid of live interest as *rigor mortis*. Even if they could appreciate the need for the purely logical discussion, they would not have time to study it. What has been said of Fourier's theorem applies also to the large amount of advanced mathematics which is inseparably connected with recent advances in physics. The traditional 'mathematics subsidiary to physics' is now quite inadequate, but experimental physicists cannot afford the time needed for a great extension of the mathematical course on its present lines.

To deal with this dilemma, the Institute of Physics and the Mathematical Association have held a conference and issued a joint report, "The Teaching of Mathematics to Physicists" (Institute of Physics, Spencer House, South Place, London, E.C.2). They recommend courses much wider in scope but simpler in technique than the usual subsidiary mathematics. For example, their Schedule A, which is to cover the minimum requirements of a fully trained physicist, includes roughly the contents of both the two subsidiary subjects pure mathematics and applied mathematics (which are alternative subjects at some universities, such as London), with the addition of a little statistics. This doubled syllabus is to be covered in the same time as before, say, one third of the physicist's total study hours for two years. This is to be made possible by omitting the solution of difficult problems, and merely requiring the student to recognize the applicability of the mathematics to physics. Specimen examination questions are given to show how this can be done.

The report also gives a Schedule B, suitable for the ablest undergraduates in their third year, and a Schedule C suitable for the postgraduate stage. At first sight these later schedules seem far beyond the capacity of any experimental physicist; but, as in Schedule A, it is intended that they should be treated with the minimum of technique. It is admitted that this will require special lectures and an increase in university staffs. It is suggested that such lectures

might be useful for students of other branches of science, but this has not been discussed in detail. It is recommended that the lecturer should be a member of the mathematics department, with a special sympathy towards the outlook of the physicists.

As a personal comment on these proposals, it may be stated that an optional course on these lines, as a supplement to the usual subsidiary mathematics, has been given for several years at University College, Nottingham. It seems to be appreciated by the stronger physicists, but it is rather a strain on the weaker ones. The surprising thing is that it is enjoyed by mathematicians, who apparently welcome a temporary release from the inhibitions of mathematical rigour.

H. T. H. PIAGGIO.

# BIOLOGICAL APPLICATIONS OF THE ELECTRON MICROSCOPE*

By DR. G. E. DONOVAN

ELECTRON micrographs may be considered analogous to X-ray pictures, since the darkness and brightness depend on the thickness and density of the specimen; they are unlike micrographs taken with the light microscope, in which an image is formed due to differences in the amount of absorption or refraction within the object. The presence of very small particles in specimens for examination under the electron microscope will cause perceptible scattering, and the image formed of an object thicker than about 0·5 μ is merely an enlarged silhouette.

Another characteristic, which is usually an advantage, is the great depth of focus. This is useful for stereoscopic work.

## Specimen Mounting

The vast majority of microscope specimens must be mounted upon a transparent support. Glass of a convenient thickness is the most suitable material when the illuminant is visible light, but it is opaque to an electron stream, and a new technique has therefore been built up, whereby specimens may be adequately prepared for examination. A very thin, uniform film of collodion or nitrocellulose can be produced so as to show no structure, similar to the glass slide used for supporting specimens in the ordinary microscope. It produces a uniform diminution of intensity, but if the film is thin enough, the amount of scattering and spread of velocity caused by it does not cause much interference with the picture. A very thin film is produced by dropping a small quantity of a 1·5 per cent solution of collodion in amyl acetate on water saturated with amyl acetate. The film spreading over the surface is taken up and dried on a small circular disk of 200-mesh wire gauze, less than ⅛ in. in diameter. Gentle pressure on the diaphragm causes it to adhere to the film. Films of this kind are thinner than the length of a collodion molecule. The coated disks are separated from the rest of the membrane by means of delicate handling tools, lifted from the water, inverted so as to bring the film side uppermost, and placed upon a miniature pedestal. There the water clinging to the surface is removed, and a drop of a fluid containing the specimen in suspension, or solution, is placed upon it, and the fluid allowed to evaporate. The whole is then placed in position on the 'cartridge', which in its turn is inserted through the air-lock into the microscope into the space about to be evacuated. The surfaces of certain materials, for example, metals and alloys, can be studied by light reflected from them in the light microscope, but this is generally impracticable with electron rays. A cast of the surface can be made by using some sort of plastic in solution and allowing the solvent to evaporate; a negative solid replica of the surface structure can be produced by peeling off the film from the original, and can be examined like an ordinary specimen in the electron microscope. An electron image of such a film will develop more strongly where the plastic material is thinnest. In some cases, where a replica cannot be stripped off, satisfactory results can be obtained by dissolving the original in some acid or other solution which the plastic film can withstand. The cast technique may be useful for examining the surface of such structures as metals, teeth, etc.

* From a paper on "The Electron Microscope: its Applications to Medicine" read before the Royal Society of Medicine on June 21.

## Practical Applications

Until very recently, the electron microscope remained an experimental instrument in the hands of the physicists, and it is only in the last few years that any serious attempt has been made to exploit its possibilities for research. Most of the examinations so far reported have been directed towards the discovery of possible fields of research, rather than towards the solution of particular problems. It holds great promise in almost every field of science, especially in chemistry, metallurgy, medicine and biology, as it reveals many important structures and reactions which have hitherto been inaccessible to direct observation and measurements.

Dusts and smokes are among the simplest kind of materials to view in the electron microscope, revealing groups of ultra-microscopic particles that float in the air. This type of research is of interest to the public health worker and those interested in environmental diseases, such as the medical man in industry, etc. A great number of the particles found in human lungs are smaller than 5 μ in diameter, and an appreciable portion less than 0·2 μ. Electron micrographs have been published of smoke particles resulting from the combustion of zinc, magnesium ribbon, aluminium, etc. The physical structure of these varies; for example, the electron micrograph of magnesium oxide shows small cubic crystals, aluminium oxide smoke is made up of strings of spherical globules, etc.

Powders are required for many purposes, and a knowledge of their physical structure is of importance. A sample of lead arsenate insecticide which possessed unusual covering power and toxicity showed under the electron microscope, magnification 56,500, that the particles consisted of extremely thin flakes, which naturally possess a large surface and clinging power. A popular face powder owed much of its popularity to the fact that it did not easily come off. The electron microscope showed that its particles were of a highly angular shape, capable of hooking themselves into the epidermis.

The instrument has many uses in organic chemistry; for example, an electron-micrograph has been published[1] showing a specimen of polyvinylchloride. The magnification (100,000) shows the specimen to be mottled with an evenly spaced succession of spots. The spots are considered small enough to constitute single molecules, and there is little doubt that visual

confirmation is here obtained of the truth of the molecular theory. It has been used in the study of protein molecules[2].

It is now possible to obtain electron micrographs of the location of certain chemical reactions incident to the metabolism of the bacterial cell. The reduction of potassium tellurite by *C. diphtheriæ* has been studied[3]. It has been demonstrated that tellurium crystals form in all parts of the micro-organism, in some cases puncturing its walls. A method of selective micro-chemical analysis has been developed[4] by taking electron pictures of bacteria after exposure to salts of heavy metals. The electron microscope has demonstrated changes in the bacterial cell brought about by the action of germicides and anti-bacterial substances[5]. The recording of the action of germicide agents on individual bacterial cells is a promising field of application of micro-chemical analysis.

Electron micrographs of bacteria have been published[6]. The *Myobacterium tuberculosis hominis* shows that its cell wall appears to be very delicate. Many small dark granules appear throughout the field, and in particular, adhering to the cell wall. Large black granules are shown within the protoplasm. A strain of Fusobacterium shows dense areas, but in contrast to that of the tubercular bacilli the dense areas are not localized in definite circumscribed granules. Monotrichates, for example, *Vibrio schuylkiliensis*, show a cell wall. Definite circumscribed granules are again seen within the protoplasm. The flagella of monotrichates—for example, vibrios—are on the whole wider in diameter than those of peritrichate and lophotrichate species. Unstained diphtheria bacilli show definite polar bodies. *Treponema pallidum* appears to have flagella-like processes at various points along its course. The morphology of *Leptospira ictero-hæmorrhagiæ* and *L. canicola* has been investigated[7].

If suspensions of streptococci are subjected for a short period to sonic vibrations, some of the cells are cytolysed[8]. These bacteria retain their original outline, but become transparent to the electron beam, appearing as pale grey bodies and contrasting strongly with the opaque normal cell. *B. subtilis*, after subjection to sonic vibrations, is shown to have the flagella continuous with the cell wall.

The combination of antibodies with flagella and somatic antigens has been demonstrated by the electron microscope[4]. It has long been known that the bacterial cell wall and flagella of organisms such as the bacilli of typhoid and paratyphoid are altered by the deposition of antibodies, and the combination of antibodies and antigens at bacterial surfaces has also been shown by quantitative analytical methods. These sensitized surfaces have now been examined under the electron microscope, and, as a result of the deposition of homologous antibodies upon them, the walls are found to become opaque, and less clear-cut in outline. The flagella become thicker, but less sharp and less uniform in outline, and they tend to coalesce.

The various viruses differ greatly in size, although each kind of virus is itself very uniform in size. During the last decade, a few of the viruses which attack plants have been isolated. Although they differ from each other in stability and analytical composition, all those purified have been shown to consist solely of nucleo-proteins of high molecular weight. These viruses seem to be a connecting link between living and non-living matter. They are actually protein molecules possessed of certain definite biological activity. On the other hand, there are viruses, that of vaccinia, for example, and all the Rickettsia disease agents, which are very much larger, and cannot be regarded as single molecules. The larger viruses appear to be true micro-organisms which can only live a parasitic existence. One of the first viruses to be photographed under the electron microscope was that of tobacco mosaic, and it at once confirmed the suggestions, based on other methods, about the size and shape of this virus. It was a rod about 300 mμ long. Particles of tobacco mosaic virus appear in purified form as discrete rod-like units with a tendency to side-to-side and end-to-end aggregation. The electron microscope has also been used in the study of the virus of tomato bushy stunt. The reaction between tobacco mosaic virus and its antiserum has been studied by means of the electron microscope[9]. This instrument has been used in the investigation of the morphological structure of the virus of vaccinia[10]. The elementary bodies of vaccinia are rectangular in shape, resembling a brick, and contain five areas of condensation, and are somewhat like the five spots of a dice. Sharp[11] and his colleagues have employed the electron microscope in their investigations of Western strain equine encephalomyelitis virus. Taylor and his associates have used this instrument on the Eastern strain equine encephalomyelitis virus. Studies have been published[12] on the nature of the virus of influenza with particular reference to the dispersion of the virus of influenza A in tissue emulsions, and in extra-embryonic fluids of the chick. The size of the infectious unit in influenza A has been investigated[13]. This instrument has been employed on the morphological structure of rickettsiæ[14]. It has also been used in studies on the papilloma virus protein[11].

Studies of bacteriophages[15] disclose an extremely constant and characteristic sperm-like appearance with a round head, and a much thinner tail; in many micrographs the head is filled with a dense internal structure. These are adsorbed to their specific micro-organisms by head or tail, and, after contact, it is possible to observe extensive damage of the bacterial cell. These results are interesting, as some years ago the bacteriophage was looked upon by some workers as of macromolecular nature. The discovery of such constant and detailed information is of interest also to geneticists, for genes are thought to be macromolecular entities. The sperms of the lamb and bull, due to their extreme flatness, are amenable to examination, and have already come under observation.

The electron microscope is of value in histological research. It has revealed characteristic cross-striations in collagen fibres, and the effects of various physical and chemical conditions on the fibres has been investigated[16] in a search for further knowledge of the molecular structure of collagen. To entomologists, this instrument shows hitherto unseen structures, and it allows the accurate measurement of those already recognized. The tracheæ, trachioles, air sacs, wing scales, and cuticle have been examined, and experiments[17] on the mode of penetration of the cuticle by non-volatile oils serve as an example of future useful applications.

The foregoing are only some of the many fields in which an electron microscope is useful.

## Some Disadvantages

The electron microscope is not yet an instrument for every pathologist's bench, due to its cost, size and complexity. Its immediate future lies rather in

the research laboratory. The bombardment of specimens with high-speed electrons produces changes in protoplasm, and in molecules. Entomologists have remarked on shrinkage, evolution of gas, discoloration, and increased friability of their specimens. As the specimen for study must be placed in a high vacuum it must, therefore, be dry. Great difficulty is experienced in viewing anything but 'dead' specimens, and in consequence, movement must inevitably be 'frozen', and require a number of successive and similar operations to show progressive action. The objects to be examined must be extremely thin.

### Some Further Developments

Due to the very small aperture of the electron rays, the electron microscope shows a surprisingly large depth of focus. Electron stereomicroscopy has been suggested by E. Ruska. M. v. Ardenne[18] has further developed this idea, and introduces in his electron microscope a particular object carrier which can be tilted by a few degrees between two successive exposures. A vivid impression of solidity is produced if the two corresponding photographs are examined under a stereoscope.

v. Ardenne has successfully applied dark-ground illumination and obtained resolving powers down to $5 \times 10^{-7}$ cm., and he discusses[19] in this connexion the possibility of viewing single atoms, and studying their distribution in the object plane. There are, however, great practical difficulties; for example, the exposure time would have to be increased more than 1,000 times if ultra-microscopical methods were to be introduced.

O. Scherzer[20] discusses the possibility of improving the resolving power of the ordinary electron microscope with direct illumination by an improvement of the electron lenses leading to larger numerical apertures. He mentions in this connexion the practicability of correcting spherical aberration by introducing space charges into the lens. F. H. Nicoll in his patent proposal of 1936 discusses the introduction of an electron mirror into the instrument. As it is feasible to construct mirrors with negative aberration, a useful opportunity of correcting the mirror-microscope is given.

The most direct method of improving the resolving power is to use appreciably greater electron energies, and thus shorter wave-lengths. There is an upper limit to what we can hope for in this direction.

After the War is ended, there should be great developments in television, and some of this research work will be employed in improving the electron microscope.

# NEWS and VIEWS

### Dr. W. K. Gregory

DR. W. K. GREGORY has recently retired under an age limit from the staff of the American Museum of Natural History. For some forty years he occupied a very special place in that great institution, for his knowledge of comparative anatomy extended over the whole range of vertebrates, both recent and fossil, and his philosophical mind led him to make wide ranging comparisons and detailed analyses of structure which have contributed very greatly to our understanding of structure and especially of the course of evolutionary processes. His early works on Tritubucular teeth and on the orders of mammals were of great importance, and were but the harbingers of many others which have since appeared. During the past twenty years his immense experience of mammalian structure has enabled him to contribute much to our understanding of the significance of the many fossil human skulls which have become known, and he has at the same time devoted much attention to the detailed structure of modern fish. But Dr. Gregory's retirement is only from his formal position; relieved of administration he may, we hope, continue even more actively his own researches.

### Prof. James Drever

PROF. JAMES DREVER has recently retired from the chair of psychology in the University of Edinburgh, which he has held since its foundation in 1931. In 1918 he was elected to the Coombe lectureship in psychology at Edinburgh, and in 1924 he became University reader. When lecturer he had eighty students, and an assistant to help him. Shortly before the present War, the number of his students had increased to nearly six hundred, and his staff comprised a reader, two lecturers and four instructors. Prof. Drever graduated in arts in Edinburgh in 1893 and spent two years in studying medicine. Owing, however, to various difficulties he was then compelled to become a schoolmaster. But in 1907 he became assistant to the professor of education at Edinburgh, where he founded the Educational Laboratory, taking a keen interest in problems relating to human instinct, in the treatment of delinquent and difficult children, and in the institution of the degree of bachelor of education and of postgraduate psychological research for students of education. These early efforts led to his later work on the psychological treatment of the psycho-neuroses, on developing performance tests of

intelligence, on colour-blindness, and on instituting university teaching in medical and industrial psychology. His son has been appointed by the University to succeed him in his professorship.

## Industrial Relations and the Cost of Living Index

A BROADSHEET "Wages and the Cost of Living Index" (No. 220) issued by Political and Economic Planning gives a useful brief review of the cost of living index itself and of the wage systems in the building and civil engineering, railways, iron and steel, coal and cotton industries and the Civil Service in Great Britain. The broadsheet forms part of a report on industrial relations which P E P is preparing, and does something to meet the need for a study of wages and other aspects of industrial relations which such innovations as 'pay-as-you-earn' have intensified. In addition to its descriptive part, the broadsheet includes the general conclusion, first, that if wage policy were sufficiently well co-ordinated between workers and employers and between different industries, it could be arranged that wages should not fall as much as prices during the down-swing, and that in return they should not be pushed up so much when prices are once more rising. Such a policy has been put into practice in Sweden with results that open up a vista of possible 'trade-cycle bargaining', under which the application of sliding scales as we know them would be inappropriate. From the workers' point of view it would be wrong to peg wages to the cost of living and thus stabilize real wages when their productivity is increasing and prices falling, for this would mean that their share in the product of their labour would be declining. One may expect that if post-war employment succeeds in producing a steadily rising national income, workers in most industries will prefer to rely on their bargaining power rather than on automatic scales. Part of the dynamic of a full employment policy must be the general striving for an uninterrupted rise in the standard of living, and therefore in real wages.

Where the workers in an industry have little expectation of increasing their standard of living, they may decide that the sliding scale will at least help to maintain their real wages. What is good for one industry, however, may not suit another; and the different sliding-scale schemes have different effects on the internal wage structure of the industries concerned. Cost of living calculations will remain of the greatest importance whether or not an automatic sliding scale is used. The minimum or subsistence allowance, in terms of money, for example, fails of its purpose unless it is adjusted to cover changes in the prices of the goods needed for subsistence, and for this purpose the sliding-scale method will continue to have an obvious justification. It would seem, however, that the avowed purpose of the index, to estimate changes in "the cost of maintaining unchanged the pre-war (i.e., pre-1914) standard of living of the working-classes" has not much relevance to present-day requirements, and that separate indexes are required for various income groups and for different localities. If authoritative indexes of this kind could be provided, much that is at present contentious guesswork in wage negotiations would be based on measurement and calculation, and the application of an accurate series of cost of living indexes would not be confined to wages but should form an essential part of national statistics.

## Sunspots and Human Affairs

Two papers by W. G. Bowerman (*Pop. Astron.*, **52**, March, April, May, 1944) discuss the rather indefinite subject of the relations between sunspots and terrestrial conditions. The first illustrates a close parallelism between sunspot numbers and the total mortgage loans on residential property in the United States. This held during 1923–38 but broke down in 1939, presumably owing to the disturbance caused by the War. The second and longer paper describes in a 'popular' manner the quasi-periodic nature of outbreaks of sunspots and a good deal of recent American literature on relations between sunspot numbers and extremes of temperature and precipitation, as well as such indirect effects as industrial activity, forest fires and outbreaks of tropical diseases. The author accepts the views of Ellsworth Huntington and C. A. Mills that the major economic and cultural cycles of historical times result from long-period oscillations of solar activity, acting through *average* temperature, which in turn controls both the spread of disease organisms and the power of man to resist or cope with them. Within the 11-year cycle there is a 'sharp upthrust' of temperature near sunspot minimum, but the relations are complicated by volcanic eruptions.

The whole subject of the reaction of man with his environment is of considerable interest and importance to students of human affairs; but it is far too complex for superficial or partial studies to have any value. For example, the author refers casually to the effect of air-conditioning of hospitals in counteracting climatic control of disease; but he overlooks Major Markham's hypothesis that the poleward march of civilization is a function of the efficiency of house-warming. There is room here for a new system of philosophy, but the first necessity is to verify and comprehend the facts.

## Structure and Classification of Bees

THE *Bulletin of the American Museum of Natural History*, **82**, 1944, contains a very comprehensive memoir on the above subject, written by C. D. Michener, an assistant curator of the Museum. The method which the author has adopted is to make a detailed study of the morphology of a single species of bee, for example, *Anthophora edwardsii*, and then to compare numerous other bees with this species. Finally, with these comparisons as a basis, the author gives an account of the interrelationships of the various groups of bees followed by a general scheme of classification. The latter deals with all groupings, from families to genera, represented in America north of Mexico. The memoir is one intended for the specialist on the order Hymenoptera. The anatomical section is concerned with external organs and parts only; the internal organs and musculature being outside the scope of the work. A certain number of new terms are used including the expressions mesosoma and metasoma for the regions commonly referred to as 'thorax' and abdomen respectively. Six families of bees are recognized. The Colletidæ and Halictidæ are the two oldest groups. The next in order of antiquity are considered to be the Andrenidæ and Apidæ followed doubtfully by the Megachilidæ. The last family—the Melittidæ—is too imperfectly known to suggest its position in the series. The largest family is the Apidæ which is held to include a large number of bees usually considered to be outside its limits. The author mentions that cer-

tain of these have often been placed in separate families largely on the basis of the presence or absence of the pygidial plate. This character is regarded as being unreliable since it is often lost in very different bees.

## Glossary of Communicable Diseases

A LIST of terms in the main European languages and in Latin denoting the various communicable diseases has recently been published ("Lexique Polyglotte des Maladies Contagieuses" (Polyglot Glossary of Communicable Diseases). By Dr. Yves Biraud. (London: Allen and Unwin: League of Nations Publications Dept., 1944. Pp. 354. 4*s*.). The author states in his introduction that circumstances did not allow of the sending of *questionnaires* to medical authorities of the various countries or of submitting proofs of the Glossary to them. This is quite obvious, and anyone looking for an accurate guide of this type will be well advised to await the appearance of a heavily amended second edition.

The term communicable is very widely interpreted, and the lists include appendicitis and Ludwig's angina, osteomyelitis and pemphigus of unspecified type. Catarrhal jaundice is listed twice, although this probably erroneous term for infective hepatitis is now nearly obsolete. Herpes zoster and herpes febrilis are given as synonyms. Chancroid, the most specific and commonly accepted name for soft chancre, does not appear. In the section on syphilis the terms for various manifestations do not correspond in the columns for the different languages.

## Sulphadiazine Treatment of Meningitis

ACCORDING to the U.S. Office of the Surgeon General, a saving of 90 out of 100 soldiers from death by meningitis has been achieved by sulphadiazine. The death-rate from meningitis in the U.S. Army in the present War is less than 3 per cent, whereas it was 93·2 per cent in the Revolutionary and Civil Wars and 39·2 per cent in the War of 1914–18. According to the U.S. Army Commission on Meningitis, as little as two grams of sulphadiazine will banish the germs from the nose and throat of most persons for a period of several weeks.

## Pole Treatment

IN an article on ground-line treatment of standing poles (*Bell Lab. Rec.*, 22, No. 11; July 1944), C. H. Amadon discusses the preservative method developed by Bell System engineers. External deterioration of an untreated pole in service begins in the ground section with infection by wood-destroying fungi which, once established, continue there unless adverse conditions are imposed, as for example, by the application of a suitable wood preservative. Two general classes of preservatives might be used for ground-line treatment, (1) oily materials such as creosote, and (2) water solutions of toxic salts such as zinc chloride and sodium fluoride. Sodium fluoride is particularly good for penetrating the heartwood of cedar and chestnut timbers, but it is not permanent. Creosote or creosote and coal tar, although not as penetrating as the water-soluble salt, is as lasting as any preservative known.

Beginning in 1935, Bell Laboratories engineers treated experimentally a total of 428 poles and posts with coal-tar creosote and other coal tar products, sodium fluoride, sodium silico-fluoride, and proprietary pastes and solutions containing preservative compounds. Periodic examinations and accumulated evidence during five years showed that treatment at the ground line with sodium fluoride and a mixture of creosote and coal tar is highly effective. This treatment effectively reduces the rate of deterioration of poles in line, and their service life (ground line condition) will be increased by about six years. This is sufficient to justify the costs involved, but an additional saving accrues from the possibility of placing pole line inspection on a six-year instead of the usual three-year cycle. The cumulative result of the ground-line treatment is a reduction in labour and expense of pole line maintenance-inspection and in the need for new poles.

## Paint Drying by Radiant Heat

IMPERIAL CHEMICAL INDUSTRIES, LTD., has recently issued a handy twenty-page booklet on this subject for the purpose of providing information on the properties of radiant heat, to indicate how these apply to the different types of plant now available for stoving paints, and how the qualities of the paints used are affected by the process. The chapter contents of the booklet relate to heat transfer, radiant heat, methods of drying paint, radiant heating equipment, radiant heating technique, and paints and radiant heat. Copies of the booklet may be obtained, free of charge, from I.C.I., Ltd., Belmont, The Ridgeway, Mill Hill, London, N.W.7.

## Seismology in China

IT is learned (*Earthquake Notes*, 15, Nos. 3 and 4; 1944) that the active recording of earthquakes is being continued in China. The Japanese invasion caused the National Geological Survey of China to change its headquarters to Chungking. The seismograph station at Chiufeng had to be abandoned. Dr. S. P. Lee has re-established the seismological work at Pehpei near Chungking. He has built a one-component instrument (north-south), which is being operated with a period of 4·5 sec. Recording began in October 1943.

## University of Bristol

THE following appointments in the University of Bristol have recently been announced:

Dr. J. E. Harris, to be professor of zoology in succession to Prof. C. M. Yonge, who has been appointed Regius professor of zoology in the University of Glasgow.

Dr. Wilson Baker, to be Alfred Copper Pass professor of chemistry in succession to Prof. E. L. Hirst, who has been appointed professor of chemistry in the University of Manchester.

Dr. A. G. Pugsley, to be professor of civil engineering in succession to Prof. J. F. Baker, who is now professor of mechanical sciences in the University of Cambridge.

---

ERRATUM.—Sachchidananda Banerjee writes, in connexion with his communication "Effect of Vitamin C on the Adrenaline Content of the Adrenal Glands of Guinea Pigs" in *Nature* of April 29, p. 526, the phrase "The adrenal glands were extracted with trichloracetic acid for adrenaline and ascorbic acid according to the method of Rees[3]" should read: "The adrenal glands were extracted with trichloracetic acid for adrenaline and ascorbic acid according to the method of Barker and Marrian[2]. The adrenaline was estimated chemically by the method of Rees[3]".

## Relationship between Sulphonation and Desulphonation

THE familiar process of recovery of aromatic compounds from their sulphonic acids is probably almost universally regarded as one of hydrolysis. We have, however, confirmed our expectation that it might be more correctly comparable with the ordinary Dumas process of decarboxylation, and so involve their anions rather than the acids themselves; for a kinetic study of the desulphonation of *m*-cresolsulphonic acid in 90 per cent acetic acid containing also hydrobromic or sulphuric acid showed its velocity to be independent of the concentration of the sulphonic acid, to conform to the first-order equation and to be proportional to the hydrogen ion activity of the solution, but independent of the nature of the inorganic anion. Sulphonic acids of mesitylene, phenol, *p*-cresol, and 4-nitrodiphenylamine, exhibited a similar behaviour.

We must therefore formulate the recognized reversible relationship between sulphonation and desulphonation as follows:

$$Ar.SO'_3 + H_3O^{\cdot} \rightleftharpoons Ar\begin{cases} SO_3 \\ H\ldots OH_2 \end{cases} \rightleftharpoons Ar.H + H_2O.SO_3$$

(I)

Sulphonation and desulphonation are thus essentially determined by the distribution of the acids, proton and $SO_3$ (in the Brönsted-Lowry sense), between the bases phenyl anion and water. Similarly the absence of oxygen exchange between sulphate ions, unless sulphuric acid be present[1], shows that here also the essential reaction is the distribution of $SO_3$ between $H_2O^{16}$ and $H_2O^{18}$ or, as it may be regarded, sulphonation of the two types of water:

$$H_2O^{18} + O_3S\,.\,O^{16}H_2 \rightleftharpoons H_2O^{18}.SO_3 + O^{16}H_2.$$

The conclusion at which we arrive in this manner, that sulphonation directly involves $H_2O.SO_3$ rather than $SO_2(OH)_2$, accords with the suggestion of Benford and Ingold[2] that nitration involves $(H_2O.NO_2)$, and the deduction by one of us[3] that nitrosation involves $(H_2O.NO)$.

Furthermore, it will be seen that in the transition complex (I), water contributes to completion of the sulphonation forces by removal of the proton in the same way as it was suggested nitrite ion does in nitrosation[3]. This is in line with the observations of Martinsen[4] on velocities of nitration and sulphonation.

This brief discussion will perhaps serve to illustrate the wider implications of our experiments for the general problem of substitution. It need scarcely be pointed out that reversibility of the sulphonation process is much facilitated by the negative charge of the sulphonate ion. The lack of such a charge in other cases commonly inhibits reversibility; but it is familiar in the cases of nitramines and chloramines, as well as sulphamic acids; and even neutral nuclear substituents may be readily displaced by proton if, for example, steric influences provide the necessary facility for attachment of proton to the nucleus[5].

It is hoped to publish a more detailed account of this work elsewhere.

## Rod and Cone Responses in the Human Eye

THERE is abundant evidence to show that the human eye has two distinct receptor mechanisms, one for vision in bright daylight and the other for vision at night. The sensitivity of the former, the photopic mechanism, is greatest for the longer wavelengths and is not much changed by dark adaptation. That of the scotopic mechanism is greatest for green and blue, and may be increased or reduced a thousandfold by keeping the eye in darkness or light. From their distribution in the retina and in different animals, the cones are thought to be the photopic receptor organs and the rods the scotopic.

A new kind of evidence for the 'duplicity theory' has recently appeared from records of the potential changes developed in the human eye. Such records have been made before without adding much to what can be learnt from animals; but with modern technique the human electroretinogram can be seen to depend on two receptor systems with the characteristic photopic and scotopic properties. Leads have been taken from an electrode on the cheek and from a moist thread in contact with the front of the eyeball. The eye is exposed to a large field lit by brief flashes of light and the potential changes are recorded by an ink-writing oscillograph. With red light, which should stimulate mainly the cones (Wratten monochromatic filter No. 70), the response is a brief diphasic change, the cornea becoming initially negative (Fig. 1*A*). This response is very little affected by dark adaptation, though there is some increase in the first few minutes. With blue light, which should stimulate mainly the rods (Wratten filter No. 76), the response is a slower monophasic change with a longer latency (Fig. 1*B*). This response is

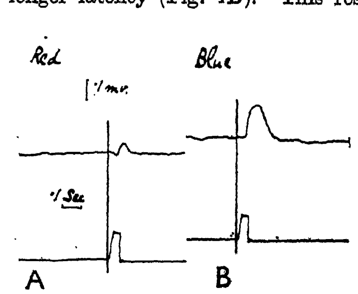

FIG. 1. *A*: ELECTRIC RESPONSE OF THE EYE TO A FLASH OF RED LIGHT. WRATTEN FILTER No. 70. CENTRAL WAVE-LENGTH 690 mμ. *B*: RESPONSE TO A FLASH OF BLUE LIGHT. WRATTEN FILTER No. 76. CENTRAL WAVE-LENGTH 440 mμ.

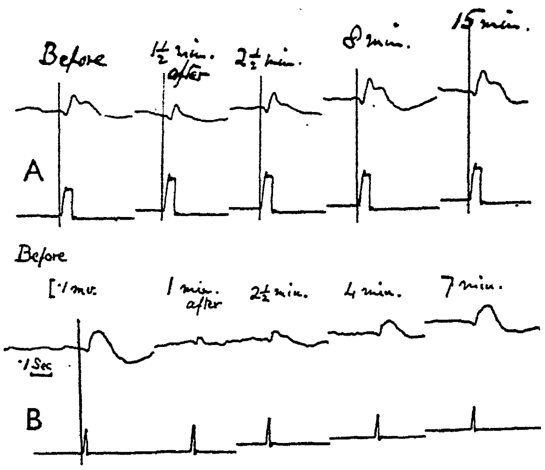

Fig. 2. EFFECT OF LIGHT ADAPTATION ON THE RESPONSE TO ORANGE-RED AND GREEN LIGHT.

*A*: WRATTEN FILTER NO. 71. CENTRAL WAVE-LENGTH 640 $m\mu$.
*B*: WRATTEN FILTER NO. 73. CENTRAL WAVE-LENGTH 575 $m\mu$.

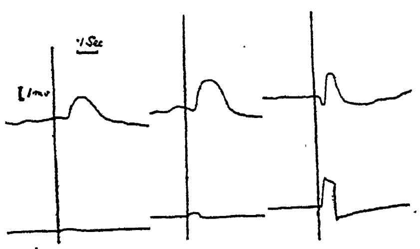

Fig. 3. RESPONSE TO FLASHES OF WHITE LIGHT OF INCREASING INTENSITY.

greatly affected by dark adaptation: it may be too small to detect (that is, less than about 20 microvolts) in the first few minutes after the eye has been exposed to a bright sky, but it will then increase steadily as dark adaptation proceeds, reaching 300 microvolts or more after 20 minutes.

With light of intermediate wave-length, the response seems to be compounded of both the rapid and the slow effects. The relative size of the two components depends on the degree of dark adaptation and can be varied by restricting the field to the central or peripheral parts of the retina, by altering the duration of the flash, or, with repetitive stimuli, by altering the frequency. Under standard conditions, the slower component is greatest with green-blue light and the rapid diphasic component with orange. The dual character of the response can be seen from Fig. 2, which gives a series of records made with orange-red light (Wratten filter No. 71) and another with green (filter No. 73). Initially the eye is moderately dark adapted, and the slow part of the response is prominent, more so in the records with green light since the slow component is relatively larger with green. Exposing the eye for a few minutes to a bright sky abolishes the slow effect, leaving only the initial diphasic response, but the slow component reappears after a few minutes and becomes larger and larger as dark adaptation proceeds.

With white light of moderate intensity the response has both components, since there is the initial negativity as well as the slower positive wave which can be increased by dark adaptation. With a bright flash, however, the slower component can no longer be seen (Fig. 3). The change in form suggests that at high intensities the photopic mechanism inhibits the scotopic, though other explanations are possible. When red or blue light is used, the form of the response, rapid or slow, is unaffected by a change in intensity within the limits of the apparatus in use.

The idea that the electric response of the retina has both a rod and a cone component is not new: it has been advocated particularly by Chaffee, Bovie and Hampson[1], but in animals other than man it has been difficult to establish a clear separation. It is easier to do this in man because the sensory performance of the human eye is so much better known.

## Proteases of Takadiastase

SOLUTIONS of takadiastase (Parke, Davis and Co., Ltd.) split casein, gelatin, leucylglycylglycine, leucylglycine and chloroacetyltyrosine. The same substrates undergo hydrolysis when the enzyme solutions are subjected to prolonged dialysis in 'Cellophane' bags against running tap water. If, however, the dialysed solutions are filtered by suction through kieselguhr layers, only leucylglycylglycine of all the above substrates is split. The addition of dialysate, inactivated by heating, does not restore the activity of the filtrates towards the other four substrates.

The carboxypolypeptidase component appears to be relatively stable, for the dialysed solutions retain about 50 per cent of their activity towards chloroacetyltyrosine after being kept at 37° for ten days. Under the same conditions, the dialysates lose 70–80 per cent of their activity towards casein and gelatin, whereas the activity towards leucylglycylglycine remains almost unchanged.

Leucylglutamic acid anhydride is not hydrolysed by the dialysates or by the undialysed solutions.

A detailed report on the foregoing and further experiments with the proteolytic enzymes of commercial takadiastase will be published elsewhere.

## Terminology of Lipoid-Protein Complexes

IN an otherwise excellent review by Lovern[1] a statement occurs on p. 32 that demands correction. In discussing the terminology of lipoid-protein complexes, Lovern rejects Macheboeuf's term 'cénapse', in favour of 'complex', claiming that the English spelling of 'cénapse' is 'synapse', to which anatomy has a prior claim.

'Cénapse' was compounded by Macheboeuf[2] from the Greek κοινός (= common) and ἅπτειν (= to fasten, tie, bind or join), with the meaning of union, bonding, binding, joining, etc. ("liaison, jonction").

It would be correctly anglicized not as 'synapse' but as 'cœnapse' or 'cenapse', and pronounced 'seenaps'. κοινός, with the meaning of 'common', anglicized to cœn- or cen- and pronounced 'seen-', occurs in many zoological terms, cœnœcium, cœnosarc, cœnosteum, cœnobium, cœnure, as well as in the more common words cœnobite or cenobite and cœnoby or cenoby. 'Synapse', pronounced in English 'sinaps', occurs with the same meaning and spelling in English as in French. It is derived ultimately from συν (= together), and ἅπτειν means literally a connexion or joining and may profitably be left with its specialized meanings to anatomy and cytology. By etymology, spelling and pronunciation, cœnapse and synapse are therefore distinctive, although their primary or literal meanings are very close.

Macheboeuf (p. 29) defines the meaning of cœnapse as follows: ". . . le terme cénapse que je propose ici s'applique non seulement aux produits créés par la saturation de telles valences residuelles*, mais encore aux produits créés par d'autres forces d'union quelles qu'elles soient, à condition que ces forces en unissant les constituants du cénapse en masquent ou modifient certaines des propriétés". Although he himself makes no claim to this ("cénapse . . . ne prejuge rien du mode de liaison") it could be argued in defence of 'cœnapse' that the prefix 'cœn-' readily suggests common or shared bonding mechanisms, that is, shared electrons of normal and particularly co-ordinated covalency, to which the more stable cœnapses such as Macheboeuf's C.A.M. are probably due; and it is not incompatible with the idea of mutual electrostatic attraction between homologous 'hydrocarbon functions' of proteins and the polymethylenic chains of lipoids, which Macheboeuf postulates to explain the less stable cœnapses. On the other hand, the meaning of 'complex', which etymologically evokes only the idea of intricate folding or entwining together, although precise enough as defined by Werner, is used in biochemistry very loosely to cover a variety of badly defined physico-chemical systems. However, my object is not so much to define 'cœnapse' against 'complex', on the grounds of precision, as to point out that Lovern's objection to 'cénapse', being founded upon an error of anglicization, is not valid.

While on the subject of etymology and correct anglicization, it seems worth while to direct attention to a misspelling of the term 'hydrophilic' as 'hydrophylic' which occurs repeatedly on p. 19 of Lovern's review and which occurs also in a communication in *Nature* by McFarlane[3]. Hydrophilic, from ὕδωρ (= water) and φιλεῖν (= to love"), hence 'water-loving', is of course the correct form in English, as is 'lipophilic', which is misspelled as 'lipophylic' in Lovern's review.

## Standardization of Root Excretions for Immunity Trials on the Potato Root Eelworm

EXPERIMENTS with South American species of potato, carried out since 1941, have shown that, compared with British species, the South American plants are generally far less strongly attacked by the potato root eelworm; nor do their root excretions stimulate to the same extent the emergence of larvæ from the cysts. A full account of this work will be published in due course. It seemed desirable, however, to describe the method recently developed in an effort to test whether the differences in excretions were truly specific, and not due to variations in the vigour of the material available for test: it was thought that this might be of use in other fields of eelworm research.

Until more is known of the nature of root excretions, their standardization, in the chemical sense, is clearly impossible. In the present method the oxygen consumption of the roots is used for standardizing the solutions of root excretions, the assumption being made that the rate of production of the latter is related to the metabolic rate. Other activities, such as growth hormone production, might similarly be used; but the former appears to be particularly suitable as it can be done reasonably accurately and rapidly, the actual determination taking little more than 5 min.

Tubers are grown in sterilized sand. When a test is to be carried out, the roots are carefully washed, and placed in tap water. Air is excluded by covering the water surface with a half-inch layer of liquid paraffin. The oxygen dissolved in a sample of the water is determined prior to the addition of the roots and again after 2 hr., when the roots are removed. Sometimes a second sample is taken after 4 hr. In these short periods the oxygen consumption of bacteria or other organisms, and the degenerative changes in the severed roots, will be slight. The dissolved oxygen determination is carried out by the Winkler method in the usual way[1]. The iodine, however, is determined with sufficient accuracy by means of a Lovibond comparator, the dissolved oxygen, in parts per 100,000, being obtained directly; but it is possible that further test may justify the use of the more accurate titration method for some purposes, such as the comparison of varieties of the British species.

If the volume of water containing the roots is increased, the reduction in oxygen concentration will be proportionately less; the converse will be the case for an increase in the amount of root. The volume of water or the actual mass of root is, therefore, immaterial, for the extent of the reduction in oxygen tension immediately indicates the amount of respiring root tissue per ml. of water. It was found that the gram or so of root generally available reduced the oxygen tension of 50 ml. of water appreciably; but smaller amounts of root and water have been used, and in one case the oxygen consumption of two 2-cm. lengths of root in 5 ml. of water was successfully measured with a syringe pipette[2]. Having determined the 'amount' of respiring root present, in terms of oxygen units, the water remaining after sampling is diluted to appropriate strength and used in hatching trials with a single-cyst technique[3]. Consideration of an actual test may serve to demonstrate the utility of the method.

A comparison of the South American species, *Solanum calcense*, and the British species, *S. tuberosum* var. Great Scot, was carried out with root excretions from tubers of similar size grown in sand. The initial oxygen tension of 1·0 parts per 100,000 was reduced to 0·6 by the British, and to 0·7 by the South American species, when the roots were removed 2 hr. later. The 'amount' of respiring root tissue per unit volume, using 'amount' for the combination of 'mass' and 'quality' concerned, was therefore greater in the former case. As the object of the experiment was to test the immunity of the South American species, the test was heavily weighted against immunity by diluting the solution from the British species twofold; the relative 'strengths', in the present sense, were now in the ratio of 2 : 3, that is, the solution from the South American was now 50 per cent stronger than that from the British species. Nevertheless the stronger solution stimulated fewer larvæ to emerge, the figures being 137 and 343 respectively, from 50 cysts; and the mean values for larvæ/cyst differed significantly. Without some method of standardization it would be impossible to say that this difference was not due to the activity of the material available; but while no finality is claimed for the figures, it is clear that in this experiment, from equivalent respiring root masses, either the South American species produced less root excretion of the same type as the British, or it produced root excretion of a different and far less effective type. It must be emphasized that the assumption on which the technique rests, namely, that the metabolic rate of root, as measured by its oxygen consumption under the somewhat abnormal conditions of the experiment, is necessarily related to the rate at which it produces root excretion, is by no means proved; however, the fact that potato root eelworm larvæ almost invariably enter the root immediately behind the growing point[4] suggests that this may indeed be so.

I am grateful to Drs. P. S. Hudson and J. G. Hawkes, of the Imperial Bureau of Plant Breeding and Genetics, Cambridge, for supplying me with the South American material for test.

## Æstivation among Terrestrial Isopoda

So far as I am aware, æstivation among the terrestrial Isopoda (woodlice) is unknown, and among the freshwater forms I know of only one example, that recorded by Mackin and Hubricht[1], who in writing on *Caecidotea spatulata* Mac. and Hubr. state, "When the ponds dry up at the beginning of summer, they burrow into the mud, construct a small cell in which they remain dormant until the pools again fill with water the following spring".

Recently, when cleaning some Petri dishes, I turned out of one a circular cake of soil ⅜ in. in thickness which, owing to its dry condition, broke into a number of pieces when laid on the bench. This particular dish had not been in use since May 10. From the broken soil two specimens of *Trichoniscus pusillus* Brandt were seen to creep slowly out. On more closely examining the pieces of the cake of soil, an empty space or cell could be distinctly made out, where these two specimens had lived for just over two months.

## Rotational Analysis of Ultra-Violet Bands of Silicon Monosulphide

SILICON monosulphide is a member of a group of diatomic oxides, sulphides, selenides and tellurides of carbon, silicon, germanium, tin and lead which has formed the subject of some recent spectroscopic investigations[1]. Its rotational constants are therefore of interest for comparison with other molecules of this group, and also for comparison with $P_2$, which possesses the same number of extra-nuclear electrons.

It was found some time ago[2,3] that a heavy-current positive-column discharge through the vapour of silicon monosulphide gave rise to a band-system in the region 2575–3875 A. The mode of production of this system in emission and the observation of a few of the stronger bands in absorption identified the carrier as SiS, and the values of the constants derived from the vibrational analysis suggested that the electronic transition involved was analogous to those responsible for the well-known ultra-violet systems of CS and SiO and the "Fourth Positive" ($A^1\Pi \rightleftharpoons X^1\Sigma$) system of CO. These observations on SiS have now been extended by a partial rotational analysis of the ultra-violet system.

The emission spectrum in the region 2800–3100 A. was photographed in a fourth order of the 10 ft.-concave grating at the Imperial College, London, the dispersion being about 1·28 A./mm. In spite of considerable overlapping and blending of the band lines, particularly near the origins, it has been possible to identify $P$, $R$ and $Q$ branches in the 0,1, 0,2, and 0,3 bands. Since the ground-state is almost certainly $^1\Sigma$, this indicates a $^1\Pi \rightarrow {}^1\Sigma$ transition, as expected. The values of the rotational constants obtained from these three bands are given below: they were derived from $\Delta_2F(J)$ differences involving only unblended lines and taking $D = 4B^3/\omega$.

| Band | $B''$ | $B'$ | |
|---|---|---|---|
| 0,1 | 0·3014 cm.$^{-1}$ | 0·2656 cm.$^{-1}$ | $B'_0$ (mean) = 0·2655. |
| 0,2 | 0·2998 | 0·2656 | |
| 0,3 | 0·2983 | 0·2654 | |

The ground-state constants can be expressed by the equation

$$B_v'' = 0{\cdot}3037 - 0{\cdot}0015_5(v'' + \tfrac{1}{2}),$$

so that $B_e'' = 0{\cdot}3037$. Although branches were followed beyond $J = 100$, effects due to $\Lambda$-type doubling of the $^1\Pi$ state were found to be smaller than the experimental error: this would be expected by analogy with the results[4] for SiO.

From the above value of $B_e''$, the value of the equilibrium internuclear distance is found to be 1·928 A. for $^{28}Si^{32}S$. This may be compared with the single-bond covalent distance as taken, for example, from the tables of Schomaker and Stevenson[5], namely, 2·15 A. The observed shortening of the length, 0·22 A., is evidence for a bond order

greater than unity and accords well with the values found for SiO (0·25 A.) and for GeO (0·15 A.)[1].

Finally, it is of interest to compare the spectroscopic data for SiS in its ground-state with those[6] for $P_2$, which has the same total number of extra-nuclear electrons ($n = 30$).

| | State | $\omega_e$ | $x_e\omega_e$ | $B_e$ | $r_e$ | $\alpha_e$ |
|---|---|---|---|---|---|---|
| SiS | $^1\Sigma$ | 749·5 | 2·56 | 0·3037 | 1·928 | $0{\cdot}0015_5$ |
| $P_2$ | $^1\Sigma$ | 780·4 | 2·80 | 0·3046 | 1·890 | 0·00165 |

The constants for the two molecules are seen to be remarkably close. The similarity in properties of the 14-electron molecules CO and $N_2$ has, however, been recognized for some time (for example, Kronig[7]), and examination of the data for the molecules with 22 electrons, CS, SiO and PN[1,6], reveals an analogous situation. Further, such data as are yet available suggest a close similarity in the properties of other sets of isoelectronic molecules belonging to these groups of the Periodic Table[1]. These relations can scarcely be fortuitous, but it is hoped to extend and perhaps confirm them by examination of other molecules of these groups.

## Banded Meson Spectrum and the Rossi Second Maximum

CHANDRASHEKHAR AIYA[1] has recently reported the interesting result that there is a discontinuity in the meson absorption curve as measured by Bhabha's method, when the total lead thickness is about 21 cm. He suggests that this has been brought out because of the special arrangement of counters shown in his communication. Bhabha[2] has also mentioned that by his arrangement of splitting lead and placing it between a tray of anti-coincidence counters actuated by showers, it should be possible to study much more accurately the range spectrum of mesons.

Though Bhabha has not indicated where additional lead is to be placed in order to study the longer range mesons, it is clear that so long as there is lead at III (see Aiya's communication) below the anti-coincidence counters, the above view is incorrect and the method cannot furnish any new information about the range spectrum. The range of mesons measured is determined by the total lead thickness, and not only by the thickness of lead above the shower-detecting tray. Further, Aiya's procedure of placing lead on top in position I is open to objections from the point of view of determining the meson spectrum. In the first place the efficacy of the optimum thickness of lead in position II in order to produce the maximum number of showers is lost as soon as additional lead is placed in position I, and in effect the arrangement nullifies the basic idea put forward by Bhabha. Besides this, the net result of Aiya's procedure is to superimpose on the meson absorption curve a Rossi curve, to be subtracted by virtue of the anti-coincidence arrangement, which rather complicates the interpretation in regard to the range spectrum.

If one does want to get a more accurate measurement of the range spectrum of mesons by preventing the effect of the secondary particles that might be produced after the mesons are stopped, one should keep a tray of anti-coincidence counters actuated by showers right at the bottom of the lead. Or better still, in order also to avoid high-energy electrons, there should be another tray after a lead thickness from the top corresponding to the maximum of the Rossi curve.

If what Aiya gets has anything to do with a banded meson spectrum, one should get it at least equally well with a straightforward counter telescope without any anti-coincidence arrangement. It seems, however, more likely that the effect is related to the second maximum of the Rossi curve. The presence of lead below the shower-detecting tray has the effect of discriminating against electronic showers, and this is probably the reason why the fall in the absorption curve due to the second maximum showers is so abrupt. Further, the fact that the fall is maintained for greater thickness of lead tends to show that the maximum is flat. This point would indeed be more clearly demonstrated if fourfold coincidences 123(45) were measured to give directly the Rossi curve for hard showers.

## Importance of Film Records

MR. OLIVER BELL, in *Nature* of August 12, suggests that the British Film Institute might "convene a Conference to obtain expressions of opinion" on the important question of the preservation and circulation of privately made films.

The Medical Committee of the Scientific Film Association has already issued a *questionnaire* to collect data about medical films with the view of raising funds to preserve those of value and, where necessary, adding titles or commentaries. It is hoped eventually to make arrangements for central distribution.

Although the first steps have been taken in the medical field, the Association is equally anxious to obtain information about all privately made scientific and technical films, and is already taking steps to send out a similar *questionnaire* to industrial firms and scientific institutions. It is also collecting information about all films suitable for technical training purposes with the view of the publication of catalogues and hand-lists of these films.

# RESEARCH ITEMS

## Fishing Mortality and Effort

BARANOFF in 1918 formulated most of the present theory of the relation of the catch to rate of fishing, rate of natural mortality, of growth and of recruitment. His exposition, in the Russian language, was, however, somewhat inaccessible, and various other workers have discovered parts of the theory without knowing of Baranoff's work. William E. Ricker (*Copeia*, No. 1; 1944) has been back to Baranoff's paper, and has also corresponded with most of the other workers interested. He has now produced a clear and comprehensive development of the necessary definitions and equations. Formulæ are derived by which the expected catch can be calculated under different rates of fishing—given knowledge of the catch at one rate of fishing, and of the rates of natural mortality, of recruitment and of growth. Such calculations are necessary for advising immediately whether increase or decrease of fishing should take place, and Ricker's statement will therefore serve a practical purpose. He realizes, however, that no method exists at present by which one can extrapolate to determine the best rate of fishing, or the yield in any state very different from the one observed, unless Graham's approximation of 1935 is generally applicable—which remains to be seen. The difficulty in applying, in extrapolation, the kind of formulæ developed by Baranoff is that the rates of mortality, growth and recruitment are expected to vary with population density (growth-rate certainly does), and the law of their variation is not known. Graham's approximation assumes a simple law, which may be too crude; but it is regarded by Ricker as possibly the most interesting recent development in the theory of fishing.

## New Fishes

IN a series of notes in *Notulæ Naturæ* of the Academy of Natural Sciences of Philadelphia, Nos. 115, 117, 119 and 120, March–April 1943, Henry W. Fowler describes several fishes which are new to science. These include a goby from the Fiji Islands, a species of Poecilia from Honduras, two new characins from eastern Ecuador and some additional new fishes obtained from the second Bolivian Expedition from the Academy of Natural Sciences of Philadelphia 1936–37.

## Tegumental Glands in Cirripedes

C. M. YONGE's work on the tegumental glands in *Homarus vulgaris* has been extended to the Cirripedes by H. J. Thomas (*Quart. J. Micro. Sci.*, **84**; 1944). As in the Decapods, the exoskeleton consists of a chitinous layer secreted by the chitinogenous epithelium, and outside this a cuticle secreted by the tegumental glands. In correlation with the sessile habit of the Cirripedes, the structure of the animal as a whole and of the tegumental glands have undergone specialization. Unicellular and compound glands secrete the cuticle of the peduncle and of the capitulum, and that of the surface of the mantle cavity is secreted by the labial and subœsophageal glands. The latter are sometimes, but inaccurately, termed the salivary glands. In the Operculata the labial glands also constantly secrete a material which entangles the waste matter entering the mantle cavity and so facilitates its removal. Apart from this activity the glands secrete only at the moult. The cement with which the animal attaches itself to the substratum is of the same nature as the cuticle, and consequently the glands secreting it are to be regarded as tegumental glands. In the Operculata, the gland cells degenerate after secretion and new cells are developed from the wall of the duct.

## Structure of the Walls of Phloem Fibres

R. D. PRESTON (*Chronica Botanica*, 7, 414; 1943) points out that there is now considerable scope for the botanist, and especially the biophysicist, to make his contribution to the knowledge of the fine structure of the cellulose walls of plant cells. Owing to their commercial value, the fibres of the phloem (sclerenchyma) have so far been chiefly studied; in these the X-ray diagram indicates the presence of cellulose chains in the longitudinal direction only, while observations on swollen walls by optical methods have led to the view that at least two layers are present and that they differ in the direction of their cellulose chains. Crossed cellulose chains definitely occur in the walls of certain algæ. The X-ray diagrams of fibres of hemp and jute reveal the presence of cellulose chains in one direction only, running parallel with the major extinction plane; this diagram remains the same for fibres of different degrees of wall thickening, suggesting homogeneity of wall construction. However, by optical examination of swollen walls in cross-section, there is indication of heterogeneity, which does not appear to be accounted for entirely by differential distribution of lignin and pectin. Differential swelling of the wall in different regions leads to the production of striations of various kinds. Also the swollen material is easily broken into separate fibrils with associated change in direction of cellulose chains, which appears to have misled at least one worker. Swelling under certain conditions produces a 'ballooning' of the outer wall layer in hemp, but not in jute, and this fact, associated with observed optical phenomena, suggests that the outer layer in hemp and the inner in jute differ appreciably from the rest of the wall. It seems clear that in such walls the aggregates of the cellulose complex must differ in their association with one another in the different layers. Comparisons with long collenchyma cells suggests that the optical heterogeneity may be due to a variation in *angular dispersion* of the cellulose chains from layer to layer; this argument is less convincing for hemp and jute fibres, but not precluded by the X-ray diagram. There is therefore still doubt as to whether any chains exist in the secondary wall of these phloem fibres other than those which run in the longitudinal direction.

## Internal Discharges in Dielectrics

A PAPER on the observation and analysis of internal discharges in dielectrics was read in London recently before the Institution of Electrical Engineers by A. E. W. Austen and Miss W. Hackett. Discharges on the surface of, or in inclusions in, insulants, constitute a particular case of a large class of discontinuous phenomena common in electrical equipment. They are important as they are a form of partial breakdown and may afford evidence of incipient failure, while also they give rise to undesirable currents and voltages. The present paper is concerned chiefly with the former aspect. In cases of gross defect or deterioration of condition, surface discharges may

be the forerunners of complete spark-over. Internal discharges may be the immediate cause of breakdown due to local overheating, but their effects are more commonly cumulative, the most important probably being the carbonization of organic insulants, resulting in field distortion and spreading of defects. The paper refers to the various detector circuits employed for observing the discharges and discusses the probable characteristics of the latter. In dealing with applications of the methods, particular attention is given to impregnated-paper capacitors and to paper-insulated cables. The conclusions which the authors have drawn from the investigation are that the validity of discharge-detection methods is established, and that, of the methods of observation described, the discharge detector approaches the form likely to give the greatest sensitivity attainable by normal methods and is satisfactory for the purpose. The oscillograph bridge, though less sensitive, is more suitable for the measurement of discharges and is capable of yielding much information on their sources.

### Rapid Estimation of Sugar in Urine

J. E. STANLEY LEE (*Brit. Med. J.*, 847; June 24, 1944) describes an improved apparatus for the rapid estimation of sugar in the urine. This is adapted for use with Gerrard's cyano-cupric method, which depends on the power of the colourless double cyanide of copper and potash to hold cuprous oxide in solution. If Fehling's solution is titrated with a sugar solution in the presence of this cyanide, the blue colour gradually fades and there is no precipitate. The colourless end-point is therefore very sharp and, because there is no tendency to re-oxidation, the process can be carried out in an open flask. The apparatus, with its graduations, is illustrated, and directions for its use are given. The apparatus can also be used for estimation by Fehling's method.

### New Complex Compounds of Rhenium

STARTING with the double chlorides of rhenium and potassium, $K_2ReCl_6$ and $K_2ReCl_5$, two Russian investigators, V. V. Lebedinskij and B. N. Ivanov-Emin, have succeeded in preparing complexes with ethylene diamine in which rhenium occurs in the cation (*J. Gen. Chem. U.S.S.R.*, **13**, 253; 1943). At first they found that it was not possible to form complex rhenium compounds by the action of ammonia, pyridine or thiourea upon aqueous solutions of rhenichlorides. Anhydrous liquid ammonia reacted with the potassium rhenichlorides, but no stable amines could be isolated, whereas with excess of ethylene diamine on saturated rhenichloride solutions there was formed a new derivative of pentavalent rhenium having the formula $ReO_2(en)_2Cl$, where 'en' stands for ethylene diamine. This compound is soluble in water and does not form precipitates with anions except cobaltinitrite and platinichloride ions. A corresponding iodide, $ReO_2(en)_2I$, much less soluble than the chloride, was obtained from it by adding potassium iodide. With hydrochloric acid the rhenyl ethylene-diamine chloride gave a hydroxy-dichloride, $ReO(OH)(en)_2Cl_2$, which could be converted back into the monochloride by treatment with sodium hydroxide. This dichloride reacted with sodium platinichloride to yield a sparingly soluble complex rhenyl platinichloride, $ReO(OH)(en)_2PtCl_6$. With potassium iodide it gave the di-iodide, $ReO(OH)(en)_2I_2$. Excess of hydrochloric acid acted upon the original chloride derivative to form a further complex compound having the formula $Re(OH)_2(en)_2Cl_3$. These are the first reported instances of complexes with rhenium in the cation.

### Periodic and Asymptotic Orbits in a Five-Body Problem

DANIEL BUCHANAN, dean of the Faculty of Arts and Science, University of British Columbia, Vancouver, B.C., has discussed this topic (*Canadian J. Research*, Sect. A, Phys. Sci.; Jan. 1944). He considers four bodies of equal mass, which remain relatively fixed at the vertices of a square, while they revolve about their common centre of gravity with uniform angular velocity. An infinitesimal body is subject to the Newtonian attraction of the four finite bodies, and the problem is to determine the orbits in which it can move. A very full investigation of the subject is given, and periodic orbits in the plane of motion of the finite bodies and also cutting this plane, and in addition, asymptotic orbits within the above plane, are obtained for the infinitesimal body moving in the vicinity of its points of libration. Four diagrams show approximate orbits for different libration points, and among these are included the ellipse, parabola, a double loop and a figure-8 curve symmetrically situated with respect to the diagonal of the square of which the finite masses are the corners. The question of the convergence of the series arises because these solutions are power series in a parameter $\varepsilon$, $\varepsilon$ denoting the scale factor of the orbits. Regarding the periodic solutions, their convergence can be established by an existing proof in which use is made of Poincaré's extension to Cauchy's theorem "Les méthodes nouvelles de la mécanique céleste" (**1**, 338; 1892–99). This shows that periodic solutions exist and will converge for all values of the time, provided $\varepsilon$ is sufficiently small numerically. Alternatively, MacMillan's theorem (*Trans. Amer. Math. Soc.*, **13**, 146; 1913) can be used. The convergence of asymptotic solutions was treated by Poincaré (see ref. above) and the conditions which he established are fully satisfied for the asymptotic orbits that were constructed.

### Distribution of Intensity within the Solar Corona

H. A. BRÜCK has described the results of a photometric study of the inner corona, especially of the region extending from 2′ to 5′ from the solar limb (*Mon. Not. Roy. Astro. Soc.*, **104**, 1; 1944). The photograph of the corona which has been used was taken by the late Prof. H. F. Newall during the eclipse of August 30, 1905, and photographic densities within the corona were investigated with the Cambridge recording microphotometer. Records were made of the variation of density along 72 solar radii, beginning with the radius in the direction from the solar centre to the north pole of rotation and proceeding along radii with equal intervals of 5° in position angle. The intensity gradients, the method for deriving which is briefly described, show in the immediate vicinity of the sun a definite correlation with the structure of the corona. Along streamers or rays the intensity decreases less rapidly with increasing distance from the sun than in normal regions. No such correlation is indicated for the region extending from 5·6′ to 8·7′ from the solar limb. An effect opposite to that found by Brück for the inner corona was observed by von Klüber for streamers extending from about 6′ to about 70′ from the solar limb.

# BIOLOGICAL RESEARCH IN THE ARGENTINE

A NUMBER of reprints from *La Revista de la Facultad de Agronomía y Veterinaria*, 10, 111, November 1943 (Universidad de Buenos Aires; Facultad de Agronomía y Veterinaria) have recently been received.

F. Monrós has a paper with the title, "Algunos coleópteros de interés forestal observados en la Isla Victoria (Gobernación del Neuquen)". Observations conducted at the Victoria island of the National Park of Nahuel Huapi, during the months of January and February 1943, enabled the author to compile a list of Coleoptera which were detrimental to forest trees. A brief outline of the ecology of the island is given with the object of locating more easily the various species which are catalogued. About a dozen species are mentioned, and a list of the families found on the island is given, with the percentage of species corresponding to each one of these. Certain species which are abundant in other parts are not found on the island, and none of the Coleoptera on the island has been discovered in the surrounding regi ns. Aquatic or sub-aquatic Coleoptera were very seldom found, and terrestrial Micro-coleoptera were poorly represented. Some species fed on decayed organic matter, and a few others lived on the flora. Other interesting information is supplied by the author, who has made a very exhaustive examination of the Coleoptera on the island.

José Vallega has a paper with the title "Razas fisiológicas de 'Puccinia graminis avenae' halladas en la Argentina", which deals with the above pest found especially in the central and northern parts of the cereal region of the Argentine. Physiological races 3 and 7 were equally abundant and had the same geographical distribution. Experiments on resistance showed that, in general, oats cultivated in the Argentine and Uruguay were very susceptible to the two races of Puccinia, but among the foreign varieties the following were remarkable for their resistance: Richland, Rainbow, Iogold, Green Russian, Hawkeye, and a number of hybrids descended from them. In addition to the genus Avena, a number of grasses showed certain degrees of susceptibility; a list of these is given. The technique adopted for the investigation of the infection, powers of resistance, and various other matters relating to the investigation, were described in detail in a previous work published in 1940.

In a paper with the title "Observaciones sobre la biología floral de *Solanum chacoense* Bitter", Enrique L. Ratera describes the results of his investigations on this species during the years 1935–42. Research was conducted at the field station of the Institute of Genetics of the Faculty of Agriculture and Veterinary Science of the University of Buenos Aires, where the species, which is self-fertilizing, flowered and fruited abundantly. Diagrams show the appearance of the flower in the early morning and at other times; the positions adopted towards evening and during the night favour self-pollination; the anthers mature simultaneously with the receptivity of the stigma. From numerous observations it appears that the duration of the flowers of the species is about 4–5 days, at least in the place where the experiments were conducted.

Juan B. Marchionatto has a paper with the title "La obra fitopatológica de L. Hauman en la Argentina" which deals with Prof. Hauman's researches, especially those of which the results were published during 1907–25. His work started in 1904 in the Instituto Superior de Agronomía y Veterinaria de Buenos Aires, which became later the Facultad de Agronomía y Veterinaria. Hauman's first results were published in collaboration with Juan A. Devoto in 1908, and were a prelude to a more important publication six years later under the title "Les parasites végétaux des plantes cultivées en Argentine et dans les regions limitrophes". As a supplementary work, which was indispensable for teaching purposes, a collection of phytopathological specimens was prepared; and it was found that a solution of copper formate preserved the colour of the green organisms as well as the vegetable structure. The most important of his studies was connected with the mutations of certain organisms in vegetables, a task on which he laboured for several years and which resulted in showing that *Mucor stolonifer* Erb. was responsible for the production of decaying matter in the potato, although other fungi and certain bacilli were capable of producing similar results under experimental conditions. A very important paper was published in 1913 in *Ann. l'Inst. Pasteur* (A 27, 501), with the title "Contribution à l'étude des altérations microbiennes des organes charnus des plantes". The results of the investigation set forth in this paper were recognized as a serious contribution on the subject of parasites of plants and their action in the production of putrefaction. The paper deals with many other matters too numerous to mention, but a summary of Hauman's conclusions regarding the factors which favour or hinder parasitism in plants is as follows: (1) conditions which determine the abundance or scarcity in the environment of the organs of propagation of the parasites; (2) conditions more or less favourable in the medium for the development of the parasites; (3) conditions more or less favourable for the reception of, or resistance to, the host.

Jorge R. Christensen contributes a paper with the title "Estudio sobre el Género *Diabrotica* Chev. en la Argentina". The author has conducted very extensive research on the subject, and supplies a list of all the species which are pests of cultivated land, and in addition, has given indications of their hosts. The paper deals with the distribution and damage caused by the pest, its anatomy and external morphology, its life-cycle, and the method for combating it. Careful observation has shown that the most effective insecticide for dusting is rotenone, using a concentration of 0·5–1 per cent. Good results were also obtained by using 'Piretrina' in a 5 per cent concentration, but, on the whole, it was inferior to rotenone. In addition to a description of new species, there are also descriptions of species studied by other authors, and thirty-two illustrations at the end of the work.

A paper by Emilio F. Paulsen and Emilio S. Lio, with the title "Sobre el Contenido de arsénico en el tabaco", deals with the determination of the arsenical contents of smoking tobacco. The arsenic serves to combat certain pests, and the plant retains and absorbs a proportion of the insecticide, the amount depending on the nature of the preparation employed and also on the method of application. Considerable differences were found in the amount of arsenic present. Thus, in the case of the black cigarettes, 10–15 parts per million were found, while the contents for Virginian cigarettes fluctuated between

5·8 and 16·6 per million. In the natural tobacco on which no work had been expended before the tests were applied, the amount varied from 25 to 250 parts per million. The data refer to tobacco grown in the Argentine and worked up in its factories, with the exception of some specimens which contained mixtures of imported tobacco, and all the data refer to the types of cigars and cigarettes which find their way into the market. The danger of arsenic poisoning from tobacco is obviously very small.

## MAGNETO-STRICTION NOISE FROM TELEPHONE WIRES

WHEN magnetic material is subjected to a mechanical force, its magnetization is changed; and conversely, if its magnetization is changed, the material expands or contracts. There is thus a relationship between the stress and magnetization of magnetic materials which is called magneto-striction. According to an article by M. T. Dow (*Bell Lab. Rec.*, 22, No. 10; June 1944), noise encountered some eight years ago on certain telephone lines was found to be caused by vibrations set up by wind in a long river-crossing consisting of steel conductors, and experiments indicated clearly that the noise was due to magneto-striction. The alternating stresses in the taut wires vibrating under the influence of wind, resulted in corresponding changes in the magnetization of the steel wires, and these magnetic fluctuations induced voltages in the wires that appeared as noise at the ends of the line.

Since the voltages induced by magneto-striction vary at rates which depend on the rates of change of stress in the wire, the noise frequencies are related to the frequencies of vibration of the wire, and these in turn are determined largely by the size of the wire and the velocity of the wind; wire tension, span-length, and other such factors also have some effect. It was found that practically all frequencies of the magneto-striction noise were in the voice range, and under certain conditions the dominant frequency was in the neighbourhood of 1,000 cycles/second, which is the range producing the greatest disturbing effect. The test results confirmed a simple relationship expressed as $f = 7(v/d)$, where $f$ is the principal noise frequency in cycles/second, $v$ is the wind velocity in m.p.h., and $d$ is the diameter of the wire in inches. To produce a 1,000-cycle noise, therefore, the wind velocity is given by the expression $v = 143d$. Commonly used copper-steel wires are of 0·104 in. and 0·128 in. in diameter, and for these two sizes the wind velocities to give 1,000-cycle noise are about 15 and 18 m.p.h., respectively. These are velocities commonly encountered.

For the same velocity of wind, the greatest effect is experienced when the wind is approximately at right angles to the direction of the wires. Taut wires with sags of less than 8–10 in. in 130 ft. spans favour the generation of magneto-striction noise. Fairly steady winds with velocities around 20–35 m.p.h. produce the highest values of noise. Winds in this range of velocity favour the building up of resonance, which leads to high amplitudes, and also are likely to produce frequencies of the greatest disturbing effect. Turbulent winds, with velocities up to 64 m.p.h., seem to inhibit the building up of resonance, and thus are less effective in producing noise. The effect is greatest in all-steel wires, and becomes less the greater the relative amount of copper.

An estimate based on a study of the results obtained indicates that for tight wires, in an exposure of 25 miles or more in length where conditions favour magneto-striction noise, the unamplified noise generated during windy periods would probably average around 28 db. above reference noise. Occasionally, maxima might reach as high as 36 db. above reference noise. Both these figures are for tight, copper-clad wire of 40 per cent conductivity; the corresponding figures for wire of 30 per cent conductivity would be about 3 db. higher. Under similar conditions, the noise for all-steel wire is likely to be 10–25 db. higher. Actually, while magneto-striction noise has been experienced with steel wire, none has ever been reported on circuits employing copper-clad wire.

## USE OF 'POLAROID' FOR THE MICROSCOPE

By DR. A. F. HALLIMOND
Geological Survey of Great Britain

FILMS of very strongly pleochroic material, usually mounted between glass plates, have been available during the past few years under the trade-name 'Polaroid'. For some purposes they can replace the nicol prism, but their use has been restricted because in a moderately strong light they transmit a noticeable reddish-violet colour at the position of extinction.

Disks of improved 'Polaroid' of high optical quality have since been made, and a British firm of instrument makers recently placed two of them at the disposal of H.M. Geological Survey for investigation of their possible use in the petrological microscope. The following is a brief report, communicated by permission of the Director, Geological Survey and Museum, on their properties, which rival those of the best nicol prisms.

*Extinction.* It has been understood that 'Polaroid' was prepared by the alignment of small pleochroic crystals in an artificial preparation. Consequently one might expect that the extinction would be less sharp than that for a nicol prism, and that a small proportion of the strongly absorbed ray would still be transmitted. For the pair of disks now to be described both these fears proved groundless.

Fig. 1 shows two examples from several curves that were measured by means of a visual microphotometer, similar in purpose to that of M. Berek, which I hope to describe shortly. One nicol (or 'Polaroid') was fixed in the usual position in the microscope, while the other was placed on the rotating stage, which could be read to 0·1°. Stray light was excluded by means of black paper tubes. With a strong beam it was possible to obtain a variation of 100 units on the photometer scale within a rotation of $\pm 2°$ from extinction. Curve $A$ is the ordinary extinction curve for two nicol prisms; there is good agreement between the photometer readings (shown by circles) and the continuous curve calculated from the usual formula, indicating that the photometer scale is practically linear. The readings along curve $B$ were obtained with two 'Polaroids'; they again show substantial agreement with the corresponding calculated curve, even for the range nearest extinction.

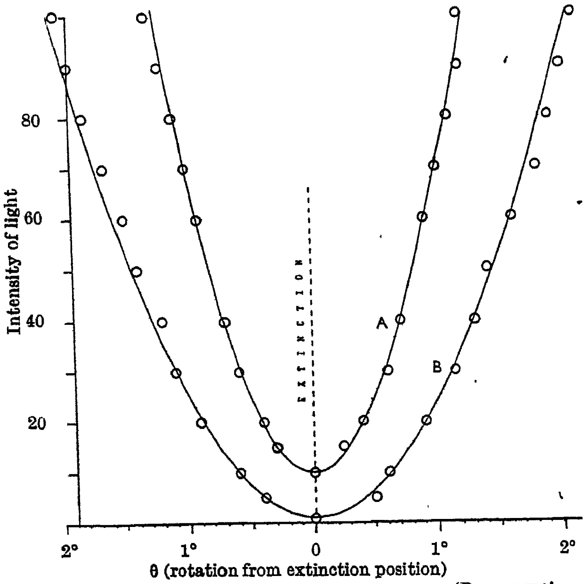

Fig. 1. Extinction curves for nicol prisms and 'Polaroids'. O, Photometer readings; full curves calculated from $\sin^2\theta$.

The intensity at extinction is not seriously different from that indicated by the curve drawn through the other readings. This curve was fully confirmed by a repetition with rather more residual light, so that the readings were from 10 units upward on the photometer scale. If the calculated curve is extrapolated to give the approximate photometer reading when the nicols (or 'Polaroids') are parallel, the percentage of residual light at the extinction position can be obtained; it is very low, being 0·0052 per cent for curve *A* and 0·0015 per cent for *B*. It follows that the absorption of the strongly absorbed ray in this 'Polaroid' is practically complete. When the sun or a lamp filament was examined directly through the crossed 'Polaroid' disks, the transmitted beam had a lilac colour, but in front of a microscope lamp it was too weak to be distinguished.

The residual light seen at extinction in the microscope, whether with nicols or 'Polaroids', is almost completely polarized by the analyser; it is thus to be assigned chiefly to the diffusion of light at the surfaces (or the admission of stray light) between the polarizer and the analyser. This is readily tested by examining the field at extinction through an additional nicol; light transmitted owing to the inadequacy of the analyser itself would be polarized at right angles to the above. The low value of the residual light in curve *B* is due to the relative ease with which the 'Polaroids' can be enclosed, and the small number of surfaces; it gives satisfactory evidence of the absence of cloudiness in the 'Polaroid' itself.

*Definition.* The 'Polaroid' disks can be made optically flat. When one was inserted in a microscope instead of the analysing nicol, the lateral displacement of the image was inappreciable and there was no apparent loss of definition. The slight displacement of focus due to the thickness of the glass was also practically negligible; if necessary, it could be completely compensated by placing a blank glass in the space usually left vacant.

*Absorption of light.* 'Polaroid' has a neutral smoky tint; measurement by the visual photometer showed a transmission of 32 per cent for green light, and later measurements gave 34 for green and 36·5 for a 'tricolour red' screen. In order to obtain a more complete determination of the absorption for the visible spectrum, the 'Polaroid' was submitted to Dr. J. McClelland at the Government Laboratory, and the following report is communicated by permission of the Government Chemist.

"The 'Polaroid' plate was fixed in front of the slit of a constant deviation glass spectrograph at right angles to a beam of light from a tungsten lamp, and rotated so as to transmit the maximum amount of light. Photographs were taken by the usual method, with exposures adjusted to give approximate equality of the spectra with and without the 'Polaroid'; the intensity of the images was then compared photometrically in a Hilger non-recording microphotometer over a series of wave-lengths. The results, one of which is represented in Fig. 2, are remarkably uniform, with a slight increase in absorption in the blue-green; otherwise there is no evidence of any noteworthy absorption band, even toward the limit of the visible spectrum."

These results imply the substantial absence of colour in the light transmitted by the 'Polaroid'. The small differences in the spectrum fall within those commonly found in the various 'daylight' screens and other sources usually employed. Of the incident light, approximately 50 per cent is completely absorbed by the polarizing action, as in the case of the nicol prism. The transmitted beam, which in a nicol would approach 50 per cent (with a small deduction for loss at the surfaces employed), is 33 per cent in the 'Polaroid', so that there is a loss of about 1/3 in the transmitted light with one 'Polaroid' and about 1/2 with two. In practice this difference seems to be more than compensated by the greater diameter at which the condenser can work when 'Polaroid' is used instead of a nicol, by the elimination of compensating lenses and by the improved extinction that may be obtained. In any event, for transmitted light there is no difficulty in using a rather stronger source. For the ore microscope the light-source is nearer the practicable limit and the aperture is often limited on other grounds; nevertheless 'Polaroid' would seem likely to be useful for all but the most exacting work on bireflexion, and for this also if a sufficient source is available.

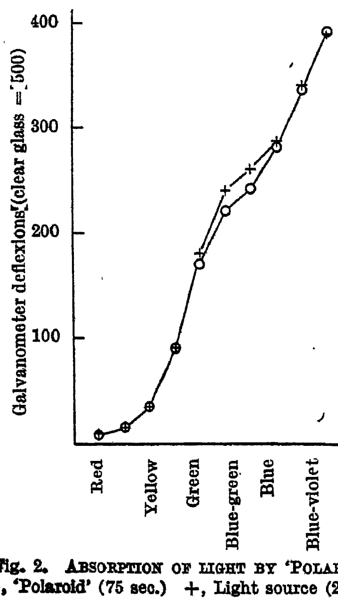

Fig. 2. Absorption of light by 'Polaroid'. O, 'Polaroid' (75 sec.) +, Light source (25 sec.)

From the preceding brief account, it would seem that the new 'Polaroid' is likely to require most serious consideration not only for students' use but also for research microscopes. Not only is there a substantial saving in cost if the material can be supplied at a similar price to the nicol prism or lower, but improvements are also possible in the optical system and in the microscope design.

## THE MELLON INSTITUTE

### WAR-TIME RESEARCH

UNDER the title "The Mellon Institute in the Second Year of War", a brief summary of the activities of the Mellon Institute has been condensed from the thirty-first annual report, indicating its contribution to the war effort. During the year, March 1, 1943–March 1, 1944, a multiple industrial fellowship on chain welding and metallurgy was divided into two separate fellowships on chain welding and on powder metallurgy techniques. The iodine fellowship was revived in April, and seven other proposals for research have been accepted. The Institute's industrial research staff now consists of 201 fellows and 214 fellowship assistants. Two of these fellowships have been active for thirty years, seven for twenty-five and eight for twenty; sixty in all have concluded at least five years of research. During the year the Institute's expenditure for pure and applied research amounted to 1,652,539 dollars. A new fellowship for research in the wood-container field is concerned to improve standards and production practices for shipping containers and also to eliminate the enormous amount of wood waste in the conversion of trees to such containers of finished lumber. A fellowship has been established to improve cotton fibres by altering the chemical structure without loss of identity or workability of the fibres, and another fellowship will conduct broad basic studies of the physical and chemical properties of cotton. A new fellowship of the Copperas Co. is devoted to studies of the oxidation products of major aromatics from tars.

Nine fellowships were completed during the year; they covered air-pollution control, anti-icing, garments, naphthalene chemistry, pasteurization, pencil technology, surgical supplies, synthetic rubber and tar treatment. Work on air-pollution control was brought to a temporary end through the death of the incumbent fellow. A report has been published on studies under the synthetic rubber fellowship of the toxicity of butadiene carried out for the Rubber Reserve Co.

The Institute's Department of Research in Pure Chemistry directed its efforts chiefly towards chemotherapy. Results obtained with certain new drugs as antimalarial agents are sufficiently encouraging to warrant further research. Under a scheme promoted by the National Research Council, arrangements have been made for evaluating the anti-malarial activity of new drugs. More than eighty new drugs have been submitted for antimalarial appraisal, and efforts have been directed towards possible ways of diminishing the toxicity of chemical structures recognized as possessing anti-malarial potentialities. Investigations on problems in the preparation of cinchona alkaloid derivatives with anti-pneumococcal potency have been terminated and the results published. Prototypes of a new class of modified cinchona derivative in which the phenolic hydroxyl group of apocupreine is replaced by an alkylamino constituent have been prepared by the Bucherer reaction, but the therapeutic action was not increased. A method has been evolved for the preparation of *p*-toluenesulphonyl esters of phenols and alcohols rapidly, economically and in high yield. A publication from the Department and the Department of Chemistry of the University of Pittsburgh deals with *cis*-3 : 6-endomethylene-Δ-4-tetrahydrophthalic acid: the anhydride of the corresponding hexahydrophthalic acid has been obtained quantitatively by direct catalytic hydrogenation under high pressure. The synthesis of 3-benzoyl-nor-camphane-2-carboxylic acid by a Friedel-Crafts reaction has been worked out.

Referring to researches proceeding in the Institute under the industrial fellowships, the report states that friction losses in vaned elbows of asbestos ducts have been determined in numerous designs; and the physical and chemical treatment of gypsum, which has received very thorough investigation during the past five years, has yielded especially valuable results in 1942–43. There are eight fellowships in all in the field of ceramics. Thirteen fellowships have been concerned with metallurgical studies and the failure of restrained welds; and the destructive testing of structural joints, involving special gaskets, has received much attention. Systems have been developed for centralized filtration of machine-tool coolants and a differential solubility process for treating waste pickle-liquor is announced. A research programme on the hydrogenation, dehydrogenation, oxidation and alkylation of coal products has been widened considerably, and several new catalytic processes are under development. A new process for ethylbenzene has been put into operation on the large scale, and another investigation has been concerned with the effect of paraffins on the nitration of toluene.

In addition to basic research on the production of phenols, another group is working on the separation of cresols and xylenols from their mixtures; new naphthalene derivatives are also receiving much attention. Studies of the rheological properties of bituminous materials have been continued, and substantial progress has been made in improving fractional distillation techniques under extremely high vacuum.

Under the seven fellowships pertaining to major problems of the food industry, improvements have been effected in dehydrating prepared foods, and new knowledge has been gleaned on decolorizing absorbents, including the evolution of a new synthetic granular absorbent for the sugar industry. In the textile field, the weathering of treated fabrics used as covers over the guns of coastal defences has been investigated to secure textiles more resistant to sun, salt air, wind and rain, and new yarns have been prepared from soya bean protein alone and with viscose, as well as a synthetic textile lubricant for the woollen industry. Reference is also made to advances in processing animal fibres used in felt and the co-relation of physical properties with felt quality. *GR-S* latex has been applied commercially to the saturation of sulphite papers, with results indicating a satisfactory comparability with rubber latex-treated papers but with somewhat less tensile strength. Growing attention to cyclopentadiene has greatly stimulated research on methods for its utilization. Compounds of interest for the manu-

facture of synthetic resins, rubbers and fibres have been prepared electrolytically and a new curable liner for container closures. New techniques have been developed for the preparation of vinyl resin coating compositions, and a thorough investigation made of the production, purification and analysis of butadiene and styrene by the multiple industrial fellowship on tar synthetics. Other studies have been concerned with specifications for metals for the construction of butadiene and styrene plant. Fundamental work has also been done on the physical chemistry of the purification of raw materials for synthetic rubber. The polymerization of butadiene, styrene and acrylonitrile are under close scrutiny, and new tests for the adhesive properties and ageing characteristics of paints and for the rheological properties of elastomeric adhesives have been adopted as guides in the development of new adhesives, while several new formulæ for 'Cellophane'-tape adhesives have been derived.

Other fellowships have been concerned with protective coatings. Several papers were published on the basic aspects of anti-fouling paint performance. Exhaustive studies of a possible accelerated corrosion effect from accidental or deliberate contact of steel hulls with the anti-fouling paint have indicated that appreciable acceleration can occur under the usual type of anti-fouling compositions containing heavy metals. The production of alkylene polyamines is being delineated precisely for industrial applications, and promising products for the synthesis of motor fuel, for the preparation of chemicals for synthetic rubber and as ingredients for lubricants, paints and insecticides have been developed from investigations on nickel compounds and catalysts. An insecticide which has given a 98 per cent kill of houseflies in the Peet-Grady chamber has been developed. Several new organic iodine compounds have been prepared in a search for improved iodine antiseptics. Work on intermediates for sulpha drugs has kept pace with current advances in this field.

Studies on the toxicity of several new products and of materials the health hazards of which were unknown but all used by the military forces or government contractors, such as dioctyl phthalate, low-temperature and extreme-pressure lubricants, insect repellents and cable-impregnating compounds have been completed.

Special reference is made to the work of the Industrial Hygiene Foundation, a non-profit association of industries for the maintenance and advancement of healthy working conditions, which has its headquarters and a multiple fellowship at the Mellon Institute. This Foundation has continued its investigation of sickness absenteeism commenced in 1941. It has given some attention to the placing of disabled soldiers who are returning to the United States and has conducted some fifty plant hygiene surveys, including exposures to such substances as synthetic resin dust, trichloroethylene, hydrogen fluoride, carbon tetrachloride, and excessive temperatures. The Foundation has continued to support medical investigations at the Saranac, New York, Laboratory under L. U. Gardner, covering disability through silica compounds and the effect of aluminium therapy. A grant was also made by the Foundation during the year for a plant investigation of health problems of women in industry. Publications on health problems of women in industry as well as on putting the disabled soldier back to work have been issued during the year.

# FORTHCOMING EVENTS

## Tuesday, September 19

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p.m.—Dr. A. Sommer: "Principles of Photo-Electric Emission and their Application in Photo-Electric Cells".

## Wednesday, September 20

INSTITUTE OF METALS (at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 2.15 p.m.—Thirty-sixth Annual Autumn Meeting. Discussion on "Melting and Casting of Bronze".

PHYSICAL SOCIETY (COLOUR GROUP) (at the Lighting Service Bureau, E.L.M.A., 2 Savoy Hill, Strand, London, W.C.2), at 3.30 p.m.—Mr. H. G. W. Harding: "Illuminants for Colorimetry and the Colours of Total Radiators".

## Friday, September 22

INSTITUTION OF NAVAL ARCHITECTS (joint meeting with the INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND) (at 39 Elmbank Crescent, Glasgow), at 2 p.m.—Dr. J. Foster King: "Longitudinal Bending Moments"; Dr. J. Tutin: "Methods of Levying Charges for Services to Shipping"; Mr. B. Alwyn Jay: "Timber in Shipbuilding".

## Saturday, September 23

BRITISH PSYCHOLOGICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Prof. J. C. Flugel: "Psychological Aspects of Moral and Social Progress" (Papers in comment by Dr. Karl Mannheim and Dr. R. H. Thouless).

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESPONSIBLE LECTURER IN PHYSIOLOGY—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (September 20).

RESEARCH ASSISTANTS (2) IN PHYSICAL CHEMISTRY (Low Temperature Polymerization)—The Registrar, The University, Manchester 13 (September 20).

ASSISTANT LECTURER (temporary) IN MATHEMATICS—The Secretary and Registrar, The University, Bristol (September 20).

RESEARCH ASSISTANT (male, temporary) in the Agricultural Entomology Division of the Ministry of Agriculture of Northern Ireland—The Assistant Secretary (Establishments), Ministry of Finance, Stormont, Belfast (September 21).

BIOCHEMIST (Reference No. F.2841.A), and a PHYSICAL CHEMIST (Reference No. F.2842.A.) at the Cereals Research Station, St. Albans—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (September 23).

TEACHER OF MATHEMATICS in the Newton Heath Technical School—The Director of Education, Education Offices, Deansgate, Manchester 3 (September 25).

QUALIFIED CIVIL OR MECHANICAL ENGINEER to teach Mechanical and Constructional Drawing—The Director of Education, The Polytechnic, Regent Street, London, W.1 (September 25).

CIVIL ENGINEER for the duties of Assistant Divisional Engineer by the Sudan Government Irrigation Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1114.A) (September 25).

TEACHER (full-time, graduate) OF ENGINEERING for Day and Evening Classes in the Crewe Technical College—The Director of Education, County Education Offices, City Road, Chester (September 26).

ELECTRICAL ENGINEER for the Nigerian Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.926.A) (September 26).

FIRST-CLASS ENGINEER to assist in Steam Turbine Design, Research and Development (location, Midlands)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2166.XA) (September 26).

CHAIR OF MINING—The Acting Registrar, The University, Leeds 2 (September 30).

DIRECTOR OF RESEARCH, Forest Products Research Laboratory, Princes Risborough—The Secretary, Department of Scientific and Industrial Research, Teddington, Middx. (October 9).

ASSISTANT TECHNICAL EXAMINING OFFICERS (temporary) in the Victualling Department of the Admiralty—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2911.A) (October 11).

LECTURER IN PHILOSOPHY—The Very Rev. the Dean, Christ Church, Oxford (October 15).

ELDER PROFESSORSHIP OF ANATOMY AND HISTOLOGY in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (October 31).

DIRECTOR OF THE DEPARTMENT OF SOCIAL STUDIES, University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (Sydney, December 1).

READER IN STATISTICS who will also act as Director of the Institute of Statistics—The Registrar, University of Oxford, Old Clarendon Building, Oxford.

ASSISTANT MECHANICAL ENGINEER for the Electrical Branch of the Nigerian Government Public Works Department—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 1391).

## SCIENTIFIC AND INDUSTRIAL RESEARCH.—V

IN our survey of the strategy of research we have already noted that, in addition to their functions in training the research workers required by the nation, the universities have an essential place in the organization for research, especially in regard to fundamental research. We have still to consider the tactics by which the fullest use can be made of the universities in this organization without detriment to the highest traditions and ideals of the universities, either in teaching or in the intellectual and spiritual service of the community. Furthermore, in considering the broad objectives towards which our programmes of research should be directed we have seen the need for some co-ordinating authority in our research structure, competent to review the broad programmes, to assess their importance and relevance to national needs and to determine the gaps which may require filling or the sectors which may require strengthening, either from the point of view of scientific advance or of the needs of society.

We come now, therefore, to a fuller consideration of the type of organization which is required to serve our strategy and the tactical modifications or developments which may be desirable in the existing structure to fulfil our purposes more effectively. That existing structure has received strong criticism in recent months, and it is appropriate in the first place to consider that criticism in fuller detail. In the main such criticism has been concerned with the lack of co-ordination particularly with reference to the planning of research, as was pressed in the House of Lords debate last year and again in the debate on research and scientific knowledge in the House of Commons last April. Dr. P. Dunsheath urged in his Atkinson Memorial Lecture that industrial research requires a live central co-ordinating secretariat. That was also the main reason for the London Chamber of Commerce proposing, in its report on scientific industrial research, the establishment of a strong central research board to act as a co-ordinating and directing body for all research organizations and to be the link between the Government and the research activities of the country at large.

That criticism is also reflected in the statement of the Association of Scientific Workers, "A Post-War Policy for Science". The survey of the organization of science contained in this statement leads to four main comments. First, the latest developments in our war-time organization have not in many fields satisfactorily linked research to requirements. Secondly, lack of central direction has produced a lack of balance in the development of science, as shown by the entirely disproportionate lack of development of biology as compared with the physical sciences. Third, the same cause, and the practice of private industry, lead to unnecessary and wasteful use of scientific effort. Finally, the whole scale and scope of research appears to be inadequate to supply the country's needs after the War.

Some of these points are made also in the severe

criticism of the existing structure to be found in an article, "Research, Intelligence and Administration", by Prof. Harold J. Laski in a series of articles on "Post-War Machinery of Government" in *The Political Quarterly*. Prof. Laski argues that there is little co-ordination, no effective machinery for publicity, and no real attempt to integrate the work and needs of government departments with those of outside bodies. All major scientific institutions—the Royal Society, the Royal Institution, the university laboratories, the British Association—depend on private benefactions for their main opportunities.

Of the sixteen points in which Prof. Laski finds the present organization defective, some are clearly matters of tactics rather than organization, though they may be due partly to bad organization—for example, the inadequacy of the salaries and status of Government research workers. Mostly their relevance in this connexion is clear enough, and without necessarily accepting their validity they may be briefly summarized as follows.

The funds at the disposal of research are utterly inadequate. The pattern of administrative organization is awkward, lacking in integration and defective in comprehensiveness. The relation of research to administration is gravely defective, and the control of research is mostly in the hands of men with no serious acquaintance with the possibilities of either natural or social sciences. There is no properly thought out policy for long-term research or any planned attempt to use the universities or bodies like the Royal Society to conduct independent investigations into problems with which the community is concerned.

No proper method exists in any government department for securing awareness of relevant work achieved by scientific workers in foreign countries—a defect which is specially marked with regard to the U.S.S.R. The present system also sacrifices the endowment of research to the easy method of direct subsidy to industry, indicating a tendency to the short-term in place of the long-term view, which in such fields as nutrition is clearly detrimental to the national interest.

Relations between the Government and the social and natural sciences are in Prof. Laski's view dominated by the theological inheritance of our society and by the individualistic approach. Again, he takes exception to the age of those who are charged with the direction of these relations and he also points to the dangers in the implications of the relation between the administrator and industry in the existing system. Finally, he comments on the inherent inertia or desire of departments to let well alone, and on the slight opportunity for the research worker in the natural or social sciences to show his powers as an administrator save by accident: all the vital places are in effect reserved for the administrative grades of the Service.

Now that is a formidable list, and the gravamen of the indictment is increased by the fact that most of the criticisms are substantiated by comments in Parliamentary debates and in the numerous reports and papers on scientific and industrial research from different sources which have appeared during the last year or so. Prof. Laski's thought, however, is very clearly coloured by his political approach, as is evident from the nature of his observations on the major changes that are required. Furthermore, his preoccupation with the political—and it might be argued the party—aspect of the problem has led him to ignore the merits or advantages of the present system, and the principles which our consideration of the strategy and objectives of research has already led us to postulate.

Prof. Laski's conclusion indicates that he is concerned more with a political thesis than to elucidate the form of organization which will best serve the principles and objectives which have been adumbrated in our survey of the strategy of research. The validity of his particular criticisms may be admitted and measures must be adopted to guard against their effects in whatever type of organization of research may be set up. The nature of that organization, however, should not be dictated primarily by political considerations but by the requirements of research and the principles which in practice have best secured its effective implementation, even though the time may be ripe for impartial re-examination of the whole question of the structure of industry from the point of view of social and economic efficiency and research.

That is the main reason why, in spite of widespread recognition of many of the defects in the present organization, there has been little evidence of a demand for fundamental change. Prof. A. E. Trueman in his pamphlet "Science and the Future", for example, examines the situation far more objectively than Prof. Laski, and concludes that, so far as the planning of science is possible, it can suitably be achieved within the organization already available. The existing organization is loose and flexible, but provides a sound basis for extending a working combination of Government assistance and direction with the help of voluntary workers. While it makes possible a general control, it leaves a large measure of individual liberty, and in particular the intellectual and professional freedom which is vital.

The development or modification of existing institutions which within their respective spheres are effective is so in accordance with the tradition of British methods that strong reasons should be forthcoming before we proceed to discard them entirely and replace them by fresh instruments. No such reasons are forthcoming in Prof. Laski's criticism, which, it will be noted, is in the main of the administrative side. Much of it, moreover, is in keeping with the essential point in the criticism of the machinery of government to be found in the reports of the Select Committee on National Expenditure, in the *Planning* Broadsheets and in the earlier report of the Haldane Committee: we need effective machinery for the planning and co-ordination of general policy. In research as elsewhere, our organization must provide, in the words of the Haldane report, "for the organised acquisition of facts and information, and for the systematic application of thought, as

preliminary to the settlement of policy and its subsequent administration".

If a modified or developed organization meets this requirement we shall have met the main points of Prof. Laski's criticism, in so far as that is properly relevant to organization and is not concerned either with the quality or ability of administrative personnel or with the financing or endowment of research. There are, however, other and even more vital considerations to be taken into account before deciding on what form our structure of research should take, or what modifications may be required in the existing organization. Further, there are certain special problems at the present time which must be handled by that organization and for which new instruments may be required.

First, it follows from what we have already said regarding the precedence of personnel over organization, that our organization for research must be such that not merely does it secure the most effective use of research workers in furtherance of our research objectives, but also it maintains the enthusiasm and initiative and originality which are vital factors in creative work.

To keep the administrative side imaginatively alive to such issues and sensitive to trends of opinion may well involve further attention to the question of intelligence as part of our research structure, but that aspect can be more profitably considered with reference to the broader question of education and information in relation to the utilization and support of research. This question of freedom in relation to organization and planning is also of vital importance in considering some of those problems in the organization of research which are specially prominent at the present time, particularly in regard to the place of the universities. As has been pointed out in a recent article in *The Economist*, all the evidence points to a growing dependence of our universities upon State assistance as compared with fees or private and independent endowments.

That circumstance of itself would demand extra vigilance to ensure that there is no weakening of the independence of the universities and of the essential freedom of inquiry and of teaching. The desirability, if not the necessity, of relating the universities more intimately with the research effort of the country as a whole so as to facilitate the planning of that effort more effectively, and the obvious importance of some further measure of co-operation between the universities themselves so as to secure the adequate endowment and staffing of whatever additional schools of research or teaching may be required while avoiding redundancy, also compel consideration of new measures of reorganization from much the same point of view.

These are the reasons that have led to some attention being redirected to the constitution and functions of the University Grants Committee. That Committee, Mr. Attlee stated, has recently been reconstituted so as to permit the association with it of persons whose services are not actively engaged in connexion with a university. In the opinion of some, such as Sir Charles Grant Robertson, such a reinforced Committee should be able to sift the programme of development of each university and to analyse and value the needs not only of each institution but also of university education as a whole. It should probably also be competent to co-ordinate special departments so that there will not be avoidable duplication or overlapping, and a single university may be selected to be the institution where a particular subject can be most efficiently pursued.

That opinion is not universally shared. The British Association Committee has suggested that the University Grants Committee might function as a Committee of the Privy Council instead of, as at present, directly under the Treasury, but its report also proposed the establishment of a universities' advisory council, entirely free from Government control. That was also the proposal of the Parliamentary and Scientific Committee and of the Association of University Teachers, and has received some support in the more recent report, "Science in the Universities", issued by the Association of Scientific Workers. While, however, the Association of University Teachers visualizes the proposed council as possessing advisory functions only, some means of providing more effective central control appears to be required, as the Parliamentary and Scientific Committee and the Association of Scientific Workers clearly recognize.

The Association of Scientific Workers contemplates that the power of such sub-committees would be limited to advising when and where new departments were needed for the investigation of newly opened fields of knowledge. The University Grants Committee would normally act on their advice and provide funds accordingly, and the research committee which it is proposed each university should establish to watch over departmental activities and present a total research budget to the university for transmission to the University Grants Committee would also maintain contact with such sub-committees. This scheme would avoid rigid planning and divorce the direction of research activities from the Treasury, but it does not appear to provide a means of dealing effectively with the problem of present redundancy to which Sir Ernest Simon has so pointedly directed attention.

We may postulate, therefore, that in regard to the universities our organization for research must provide some effective means for consultation and cooperation between the universities themselves, whether through the development of the University Grants Committee, through a universities advisory council or in other ways. Next, it must establish right relations between the universities and public bodies in which the universities recognize that they are in large part public institutions with public duties to perform, in providing the education and producing the graduates the country requires. The means provided for both these purposes must safeguard the independence of the universities and of the fullest freedom of investigation and teaching while securing responsiveness to the creative forces at work in the nation as a whole.

In this question of contact between the universities and the community in the organization and planning of research, contact with industry is of special importance. We have stressed the importance of such contacts from the point of view of personnel, but more organized contacts are required from the point of view of the planning of research itself. That is the significance of the Joint Council set up by the University of Manchester and the Manchester Chamber of Commerce.

Looking at the sphere of research for which the Government may be held directly and primarily responsible, it has long been recognized that the work required to maintain accurate standards of length, time, weight, etc., is properly a Government responsibility. Research in such sciences as astronomy and geology also requires a large measure of Government security. Similarly, it is right that such specialized forms of industrial research as factory lighting and ventilation, and on industrial safety should be carried on largely under Government auspices and financed out of public funds. Much the same applies to research into questions of soil erosion, forestry, plant diseases, water supply and many other problems in the domain of agriculture or health which have a social as well as an economic bearing.

It is, of course, not easy to draw precise limits as to the extent of Government responsibilities. Already a number of Government research stations, such as those concerned with building, fuel, food, agriculture, are in effect carrying out industrial research, but generally speaking it may be said that this applies to industries which are fundamental to the life and well-being of the nation. It is to be expected that the Government will always have a special interest in the industries serving these fundamental needs, and that there should be adequate provision of research into such problems under Government auspices, especially when the industries concerned are not easily able to organize such research themselves.

From this point of view the Department of Scientific and Industrial Research has unquestionably proved its value and should be retained in our structure of research. But over a far wider field the Government should be constantly on watch for new developments in scientific knowledge which may be of economic or social value to the nation. It was very noticeable in the House of Commons debate last April that research into medical and health problems, even where they closely affect economic productivity, was largely overlooked. Nor was anything said of economic and social research, and particularly the use of scientific methods in the study of relations between human beings.

It is clear that even from the point of view of the organization of research under direct Government auspices some means of ensuring a wider view and of effectively correlating the work of the Advisory Council for Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council and the Colonial Research Council is essential, and this must cover also the whole social and economic field and provide the Government with the best impartial scientific advice on all matters of industrial development on the application of scientific knowledge. Obviously such an organization capable of supplying the necessary central direction must be related to the Cabinet and to the policy-making bodies of the various sections of the Government if it is to be aware of the national problems concerned.

These could well be the essential functions of the Scientific Advisory Committee of the War Cabinet, and Dr. Haden Guest's proposal that this should form a permanent part of our machinery of Government might in principle meet the need, though its terms of reference as set forth in the White Paper on Scientific Research and Development must be enlarged and the details will require elaboration. The Association of Scientific Workers has suggested the establishment of a National Research and Development Council responsible to the Lord President of the Privy Council. The suggestion of a Ministry of Science is unlikely to be as satisfactory for reasons which were well stated by Mr. Attlee in a reply to Mr. Wootton-Davies in the debate. Co-ordination is not the same as centralization, and it is important to retain as much flexibility as possible in our organization and to aim at the permeation of all Departments of State with some understanding and appreciation of the scientific method and outlook.

When we have thus provided for the effective organization of research in the universities and under direct Government auspices there will remain a large field of applied research to be undertaken by private industry. It must be recognized that here there can be no question of formal organization from outside, any more than there can be such organization of fundamental research at the universities. In the discussions on industrial research during the last two years, while it has been clearly recognized that the Government has certain responsibilities in this field and that neglect of research has been an important factor in the depressed condition of some industries, with consequences in the national economy which no Government can wisely ignore, there has been no suggestion that the Government should do more than provide the most favourable conditions for stimulating research, whether in its fiscal and taxation policy and by the allowances made for obsolescence or by its attention to the supply of scientific workers through an adequate policy of scientific education. The essential function is that of encouragement, and the Nuffield College statement firmly rejects the idea of direct financial aid to the research expenditure of private firms, beyond what may be granted in the form of tax remissions.

One reason for rejecting any such proposal is that no such concession would be made on general lines without extending public control over the research thus aided, and such control over industrial research in the direction of the discovery of new products and new processes or on the improvement and simplification of existing processes and the discovery of new raw materials would probably be both unwelcome and impracticable. None the less, industrial research must be included within the general framework of the nation's organization for research, partly because of this recognized responsibility of the Government

for encouraging such research in appropriate ways, partly also because of the State's responsibility for seeing that the field is adequately covered, and partly for the reason that the invaluable interchange of personnel between pure and applied research and the contacts which are so stimulating cannot be secured without some regard on the part of the State to the general conditions of industrial research.

There is another reason for some closer consideration of applied or industrial research by the State. We have already seen that in certain industries fundamental to the national welfare the Government has already in its own research stations assumed direct responsibility for much of the research required. Suggestions have also been made that there is need in Great Britain for institutions of the type of the Mellon Institute of Industrial Research or the Massachusetts Institute of Technology to provide either an organization in which research workers can be delegated to study specific industrial problems or to cover problems which are common to many industries but the concern of none in particular, as, for example, chemical engineering.

The problem is well put in the Nuffield College statement, but that statement makes no recommendation that public funds should be applied to this purpose. Clearly any such project must be carefully examined from the point of view of existing research stations or research associations and their development, and also in regard to developments at the universities. No decision on such a point could well be reached except at the level of such a Scientific Advisory Committee as we have already adumbrated.

The place of the research associations demands a little further attention. Doubts have frequently been expressed as to the extent of their effectiveness, but in view of the number of small units in many industries and the growing cost of equipment, co-operative research of this type must probably find a more or less permanent place in our research organization. Large laboratories may be required for research both of the convergent or divergent type, and it may also be advantageous for some of the smaller industries to attach themselves to research institutions maintained by larger industries which are technically related to them. Moreover, consideration must also be given to the question of the extent to which the research associations themselves would be responsible for some of the fundamental research required, thus supplementing that in progress at the universities.

The assistance or encouragement which the State may be expected to give to industrial research will thus vary with the nature of the industry and with the size of the constituent firms. It is thus imperative that our organization should be flexible and that the Government policy should be as fully informed as possible—a further and fundamental reason for a co-ordinating secretariat and information centre for industrial research. No scientific advisory council can function effectively unless it is provided with adequate and efficient fact-finding instruments upon which its policy can be based.

# FOSSILS AND ROCK CHRONOLOGY

## Index Fossils of North America

A New Work based on the complete revision and re-illustration of Grabau and Shimer's "North American Index Fossils". By Prof. Hervey W. Shimer and Prof. Robert R. Shrock. Pp. ix + 837 (303 plates). (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1944.) 20 dollars.

A CENTURY and a quarter have passed since William Smith's "Strata Identified by Organized Fossils" (1816–19), with its figures of some 160 British fossils, made the long-delayed announcement of the discovery indicated in its title. The subsequent correlation of sedimentary rocks throughout the world has largely depended on the application of this discovery. Included microfossils now often enable the oil geologist to ascertain the horizon of the smallest sample from one of his borings; coal seams may be identified by fossil shells in the associated shales. In such ways has the study of fossils become of great practical help to mankind.

There is no doubt, however, that the field geologist is now very diffident about attempting to deal personally with any fossils he may collect, so extensive is the literature and so intricate are modern schemes of classification. The work under review is a notable attempt to remove such difficulties by presenting an epitome of modern knowledge of American invertebrate palæontology. Although nominally a revised edition of Grabau and Shimer's "North American Index Fossils" (1909–10) it contains so much new matter that it may well claim to rank as a distinct work. Many leading American palæontologists have collaborated in its preparation.

An index fossil, we are informed in the introduction, is "one which identifies and dates the strata or succession of strata in which it lies", but since ideal index *species*—forms with restricted stratigraphical range and broad geographical distribution—are comparatively rare, "a *genus* which has narrow stratigraphic range and rather broad geographic distribution is now considered an index fossil". Notwithstanding its title, however, the work is by no means restricted to genera of limited range, for "some genera with long vertical ranges have been selected, not because of any particular value as index fossils but because they are common", and it has, moreover, "been thought proper to give some representatives of each of the main taxonomic groups which may be encountered in the field".

The primary object of the work is thus to serve as a guide to the identification of genera, although it will enable many species, some of use as stratigraphical indexes, to be named incidentally. By its aid it should be found possible to ascertain to what formation any assemblage of American fossils should be referred, but in subdivided formations it is no guide to the very precise horizon. Detailed zonal work, such as has been carried out at many horizons of the stratigraphical sequence by the intensive study of such groups as the graptolites of the Lower Palæozoic and the ammonites of the Mesozoic, receives no mention. The inclusion of a glossary or table of formational terms adopted in the work would have been useful, for most non-American (and probably many American) readers will probably be as ignorant of the positions of such formations as

the "Kinzers", "Hosselkus", "Steamboat", and "Pinecrest" as is the reviewer.

Grabau and Shimer's work consisted of two volumes totalling 1,762 pages; its successor contains more subject-matter, but consists of a single volume of 837 pages. The reduction, probably enforced by war-time paper restrictions, has been accomplished by the adoption of a larger format and more closely spaced type (in double columns), and by the grouping of all illustrations in plates. Considerable additions have been partly provided for by the omission of artificial keys to genera and species (such keys seldom prove of much use to the palæontologist), by the curtailment of specific descriptions, and by the omission of chapters of a general character. Owing to their comparatively insignificant type, names of orders and suborders unfortunately appear subordinate to the generic names. The illustrations, 9,400 in number, occupy no fewer than 303 plates, and their general standard is excellent. Their profusion, even if it has meant the sacrifice of a certain amount of text, is amply justified. In no other work will the palæontologist find assembled a series of figures illustrating so many genera of all groups. The figures are partly new and partly reproduced from standard monographs.

The search for oil in many parts of the world during recent years has given an impetus to the study of many groups of organisms, particularly those of microscopic size, the value of which as stratigraphical indexes was formerly unsuspected. The Foraminifera are a case in point. In the much enlarged section dealing with this group J. A. Cushman describes the smaller forms, L. G. Henbest the Fusulinidæ of the Upper Palæozoic, and W. S. Cole the Orbitoids of the Upper Cretaceous and Tertiary. In other new sections E. B. Branson and M. G. Mehl deal with the Conodonts and a group of specialists with the Ostracods. Although fossil plants as a whole do not fall within the scope of the work, a concluding chapter contains notes on a few such remains, particularly Charophyta, likely to be found in rock samples searched for other microfossils.

Far-reaching changes in classification must always present a problem to writers of reference books. Kiderlen's inclusion of the Conularida in the Cœlenterate class Scyphozoa, although far from convincing, is accepted, but the important work of Kozlowski on the affinities of the Graptolitoidea (which he transfers from the Cœlenterata to the class Pterobranchia of the Hemichorda) is ignored, as is also Withers's separation of Turrilepas and its allies from the Cirripedia as a new group, the Machæridia.

A new section on the Crinoidea, the work of R. C. Moore and L. R. Laudon, is one of the outstanding features of the work; particularly notable are its clear line-drawings illustrating generic morphology. G. A. Cooper's section on the Brachiopoda, also new, deals mainly with the Palæozoic genera, those of the Mesozoic receiving scant mention. The section on the Pelecypoda has been curtailed with only slight revision. Some genera (for example, Ptychomya) of real value as index fossils are now omitted. Much more might have been said about the stratigraphical value of the Rudists (of importance in Texas and Mexico) and of certain groups of Trigonia. Among the genotypes cited that of Anthracomya ("*Naiadites elongata* Dawson") is incorrect, that of Pecten ("*P. adscensionis* Osbeck") very debatable, and that of Janira ("*J. niternudia*" [? *intermedia*]) hopelessly misprinted. Revision of the Gastropoda section has mainly affected the Palæozoic forms, dealt with by J. Brookes Knight. The section on the Trilobita, in which several authorities have collaborated, gives descriptions and figures of a large number of new genera founded in recent years.

The high price of the work no doubt results from the profuseness with which it is illustrated. European palæontologists will find it most valuable for reference notwithstanding its purely American scope.

L. R. COX.

# THE CONSEQUENCES OF FRUSTRATION

## Frustration and Aggression

By John Dollard, Neal E. Miller, Leonard W. Doob, O. H. Mowrer and Robert R. Sears, in collaboration with Clellan S. Ford, Carl Iver Hovland and Richard T. Sollenberger. (International Library of Sociology and Social Reconstruction.) Pp. ix+150. (London: Kegan Paul and Co., Ltd., 1944.) 10*s*. 6*d*. net.

EIGHT members of the Yale Institute of Human Relations have co-operated to produce this book. The result is not a mere juxtaposition of uncoordinated viewpoints but a unity of aim and consistency in presentation which make the multiple authorship almost undetectable. Whatever judgment one may make about the value of the hypothesis elaborated in the book, there can be little doubt that the intimate collaboration of a team of specialists, each with a distinctive training, is a profitable way of examining a problem which has no clear-cut frontiers and which does not fall neatly into one of the conventional compartments of social study.

The authors begin by indicating the many diverse forms of aggressive behaviour ungeneralized under any one explanatory principle, and to meet this apparent need they set up a twofold hypothesis, first, that frustration always leads to aggression and, secondly, that aggression is always due to frustration. They proceed then to show how the theory provides one conceptual framework for a variety of human phenomena including the process of socialization in infancy and childhood, the adjustments necessitated in adolescence, criminal behaviour, the effects of differences in political organization and the structure of a primitive society.

The frustration-aggression hypothesis, in one form or another, is not new. This is recognized by the authors, who attempt to go farther than earlier theorists by giving special prominence to what they regard as the inevitable consequence of frustration on one hand and the sole cause of aggression on the other and then scrutinizing the explanatory value over a wide field of a hypothesis stressing this two-way relation.

Apparently, it was considered less important for the purpose to examine the validity of the assumptions underlying the hypothesis than to deduce corollaries which follow from it. Since the hypothesis is presented not with any finality, but tentatively, to stimulate and guide further research, this attitude can be justified. Nevertheless, the effect will be to make many readers regard the book as an exercise in deductive rather than inductive reasoning without giving them sufficient confidence in the inductive foundations on which it is based.

To make premature deductions from a generalization insecurely founded inductively leads to difficulties. Thus, on the principle that aggression is a catharsis that reduces instigation to all other acts of aggression, together with the principle of displacement, it is deduced that various forms of aggressiveness should vary inversely if original frustration is held constant. One has difficulty in reconciling this with the continued aggression in many directions of aggressor nations whose original frustration has presumably remained unchanged. Aggressive acts frequently seem to have a way of reinforcing the instigation to other such acts rather than to operate in inverse relation to them.

Until fairly recently the belief that aggression is determined by a primary instinct was widely accepted. This instinct was regarded as existing, as it were, in its own biological right and manifesting itself, so to speak, autonomously. Thanks to a growing understanding of the nature–nurture issue, aggressiveness is now thought of more as an acquired characteristic rather than as an inborn tendency. The authors' view that all aggressive behaviour is due to the impact of the environment upon the individual may therefore be welcomed in that, as a theory, it is subject to verification and tries first to exhaust the possibilities of explaining in terms of known before resorting to unknown categories.

However, certain objections to the traditional theory of aggressiveness as an innate tendency still hold against the theory under consideration. For these objections were usually based on the observed variability of behaviour in different environments, inexplicable genetically, and not in accord with a conception of mind as a rigid set of predetermined dispositions. The present hypothesis retains this element of rigidity although it abandons the notion of innate aggressiveness. Now while there is doubtless some relation between frustration and aggression, many may wonder whether it is justifiable to lay it down even as a hypothesis that frustration *always* leads to aggression. Such a theory implies an essential biological connexion holding between the two processes. But may not the relationship be culturally rather than biologically determined ? If so, it is an 'accidental' rather than a necessary association. Before this possibility can be wholly excluded, it needs to be demonstrated that no individual can respond to frustration unaggressively such as would seem to be the case, for example, in maternal conduct in general or possibly in 'turning the other cheek' or in masochistic behaviour. The eagerness to find a 'law of Nature' has evidently tempted the investigators to presume, too hastily, the existence of a necessary relationship. Since perfect interdependence of two variables rarely, if ever, seems to be encountered in human measurement, this alone would suffice to cast doubt on the validity of the hypothesis as it stands.

There is yet another difficulty. According to the view put forward, frustration and aggression appear to be opposite ends of one continuous event or experience with an arbitrary line of division between them, for if the relationship between the two processes is invariant, who is to say when the experience of frustration terminates and the impulse of aggressiveness begins ? It is doubtful whether anything is gained by defining aggression 'independently' of frustration and whether it is logically justifiable to do so.

The limited scope of the hypothesis is brought out most, perhaps, in the relatively little light it throws upon the most obvious and important kind of aggressive behaviour of all, namely, collective aggression or warfare. An early promise (p. 19) of the authors to bring "wife-beating and war" within a common universe of discourse appears to be overlooked in subsequent pages. The only serious reference to the subject is the familiar observation (p. 64) that in view of the process of displacement of aggression from in-group to out-group, "one, though only one, of the conditions of avoiding war is to diminish intra-social frustration". It may be noted in passing that there are weighty considerations against any view which sees in a group phenomenon like modern warfare merely a summation of the effects of the frustrations of individuals. For that matter, it is exceedingly doubtful whether individual frustration or, indeed, any process of individual behaviour as such, can be given any primary significance in explaining an organized group phenomenon like modern war.

The authors' treatment of criminality calls for a few words of comment. They regard the incidence of crime as a function of the discrepancy between frustration, on one hand, and anticipation of punishment on the other. If both these factors are of high or if both are of low degree, or if the former is low and the latter is high, then crimes will tend to be few ; if, however, frustration is high and anticipation of punishment is low, then crimes will tend to be many. The difficulty here, as indeed with the subject as a whole, is to find some measuring scale for the basic variables. What is a unit of aggression or of frustration ? Can we ever say that one person is twice as frustrated or twice as aggressive as another ? This difficulty is fundamental and lies at the root of mental measurement. So long as the investigator is content with statistical units or abstract frames of reference for classifying human behaviour, the difficulty can be evaded even if the results are psychologically not very satisfying. But the authors here are more ambitious. They wish to find a few common psychological denominators under which to embrace all the diverse phenomena of crime. They try to do this in an indirect way which is not very convincing. Crime is assumed to be a species of aggression simply because it is supposed to be a response to frustration. This supposition is, in turn, based on correlations between the incidence of crime and economic, vocational and educational status, intelligence, age, health, physical appearance and other factors. To use these latter observations and their interpretation as evidence of the frustration–aggression hypothesis is to beg the question. Moreover, a large proportion of crimes such as larceny or offences against property without violence do not fall under the authors' definition of aggression as "an act whose goal-response is injury to an organism (or organism surrogate)".

The fact that the divorced population provide a disproportionate number of convicted persons is regarded by the authors as "the most dramatic demonstration of all of the role of frustration in the causation of criminality" (p. 91), the assumption being that divorce is usually a frustrating event. It seems to be overlooked that divorced persons are a selected and possibly maladjusted group and, hence, whatever factors lead to the break-up of their marriages may also contribute to their increased criminality.

While feeling that the main hypothesis has not been adequately formulated, the reader will be amply rewarded by the many illuminating remarks scattered

through the pages, particularly in Chapters 4 and 5. One example may be mentioned. The authors point out that the cathartic effect of aggressiveness which follows frustration serves only to reduce the secondary instigation produced by frustration not, as is commonly assumed, the strength of the primary instigation which suffered frustration.

The frustration–aggression hypothesis, even with limited scope, is not simply of academic interest. All those charged with the care and upbringing of children, with the management of personnel in the various spheres of industrial and social life are frequently confronted by individuals in their charge who react in a hostile manner to unavoidable frustrations. This clear discussion of the problems of adjustment which individuals must face in any society should be of much practical value. Further verification of the theoretical basis will be welcomed.

JOHN COHEN.

## BERKELEY'S PHILOSOPHICAL NOTES

### Philosophical Commentaries, generally called the Commonplace Book

By George Berkeley, Bishop of Cloyne. An editio diplomatica transcribed and edited with Introduction and Notes by Prof. A. A. Luce. Pp. xlii+486. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1944.) 73*s*. 6*d*. net.

THE manuscript generally, but inaptly, called "Berkeley's Commonplace Book" is a document of unique interest in philosophical literature. Berkeley took his B.A. at Trinity College, Dublin, in 1704 at the age of nineteen. In 1709 and 1710 he published his "New Theory of Vision" and his "Principles of Human Knowledge", the two works on which his philosophical fame has always rested. Berkeley's ideas were novel, but very clear and articulate, and skilfully argued in these books. The only thinkers to compare with him, who advanced so far so quickly, are Descartes and Hume. It is most fortunate that we can examine the notebook in which he recorded his philosophical reflexions during this short period of intense mental activity. Prof. Luce considers that the notes were written during 1707–8, and that Berkeley probably had before him a preliminary draft of his theories. Thus the "Commonplace Book" shows how his first thoughts were altered and improved until they attained their first published form, never greatly altered alterwards.

The manuscript was discovered by Campbell Fraser and published in 1871 in his edition of Berkeley's works. Unfortunately, Fraser failed to notice that the two notebooks Berkeley used had been bound together in the wrong order, so that his text is confusing. G. A. Johnston's edition of 1930 corrects the principal error in chronological order. Prof. Luce, however, finds that Johnston has still got some entries misplaced. There are also other inaccuracies in the two earlier texts. Moreover, the original document was damaged by sea water when Berkeley had it with him on his travels. Parts were difficult to decipher in Fraser's day and are now much worse. Prof. Luce has therefore undertaken to produce a complete type-facsimile of all the entries of philosophical interest, with erasures, alterations and later remarks all in place. In addition he has provided copious and very necessary notes, cross-references and indexes. The value of these can be seen by taking an example at random. Entry No. 526 reads: "Locke says the modes of simple Ideas besides extension and number are counted by degrees. I deny there are any modes or degrees of simple Ideas. What he terms such are complex Ideas as I have prov'd by Green". This is cryptic enough. However, given the correct reference to Locke, to several other entries in the "Commonplace Book" and to Berkeley's published work, we can then see how Locke's tentative, stumbling but very suggestive analysis of perceptual processes stimulated Berkeley's more precise mind; how Berkeley gradually clarified his own thinking and terminology to produce a different, far more definite (perhaps more erroneous) statement. Prof. Luce provides a guide to these interconnexions that will save readers much hard work and many misunderstandings.

Students of Berkeley for many generations to come will be grateful to Prof. Luce for this fine piece of work, to his publishers and printers who have shown that good craftsmanship is still possible after nearly five years of total war, and to Trinity College, where Berkeley's thinking was fostered and where his memory is still honoured as it should be.

A. D. RITCHIE.

## AN ASTRONOMICAL TEXT-BOOK

### Elementary Mathematical Astronomy

By C. W. C. Barlow and Dr. G. H. Bryan. Fifth edition, revised by Sir Harold Spencer Jones. Pp. viii+388. (London: University Tutorial Press, Ltd., 1944.) 12*s*. 6*d*.

THIS book belongs to the peculiar class intermediate between the popular work on astronomy on one hand and the serious technical treatise on the other. The scope of the class is otherwise not easily defined in precise terms. Sir Robert Ball, who made a distinctly elegant contribution to it, confessed that the effort had caused him great and apparently unexpected difficulty. Simon Newcomb, whose work on the popular side had been as conspicuously successful as his labours in mathematical astronomy were of the most distinguished, once ventured into a similar field belonging to neither. In acknowledging frankly an error brought to his notice he showed him self-conscious of a pitfall to which the expert is liable in the attempt to make a statement adapted to the intelligence of readers less gifted than his usual audience.

Neither of the two original authors of the present text-book belonged to the ranks of the professional astronomer. That it possessed merits of a distinct kind is attested by the fact that it has outlived half a century, during which it has reached a fifth edition, while the number of impressions demanded has been far more numerous. The third edition (1923) received the revision of Dr. A. C. D. Crommelin. But it may be suspected that the survival of the book is due in no small degree to the English mania for examinations and the demand fostered thereby. It has now received a fresh lease of life at the hands of a most eminent editor who has done his work well. Yet there remain traces of that aridity which is a natural outcome of its origin. It may be hoped that when war-time restrictions are removed an editor so eminently qualified will see his way to expound the subject with greater freedom in his own manner.

In 1892, when the book first appeared, astronomy seemed to have reached a peculiarly static position, in reality the unsuspected precursor of an outburst of creative activity. In particular, the Nautical Almanac seemed to have attained a settled form unlikely to be changed for years to come, and with it the outlook of the student was bounded accordingly. Now the conditions have changed, including the definition of time; the Nautical Almanac itself is not the same, and it has been supplemented by the abridged edition for the use of seamen and the Air Almanac for the special needs of air navigation. Moreover, the students are not the same; their interests are professional and no longer merely academic. Thus the opportunities which face the instructor in astronomy are vastly more interesting than existed half a century ago, and they are different in kind.

The more spectacular modern changes in the subject-matter of astronomy itself may seem to be associated with the introduction of physical methods and ideas. But the Astronomer Royal has confined his revision to bringing up to date the exposition of those fundamental principles on which the whole subject depends, to rearranging related sections and to providing a sound introduction to the methods of sea and air navigation now in use. An enlarged table of astronomical constants has been added. But in the main the substance of the work remains as in earlier editions. In abstaining from incursions into astronomical physics the editor is doubtless justified by the proved success of an existing model. Even without transgressing the limited ideas of the nineteenth century some relief to the purely goniometric line of argument might be found in the conception of radial velocity and in the rectangular co-ordinates appropriate to photographic projections. Without going so far the Astronomer Royal has greatly improved the structure of the work and made many necessary alterations within its familiar framework. But if in happier days a fresh edition is contemplated, one is tempted with all respect to exclaim with Hamlet, "O! reform it altogether". In short, let it be a new work inspired with the aim of serving as the master, not the servant, of the examiner. H. C. PLUMMER.

## CHEMISTRY OF WHEAT

**The Constituents of Wheat and Wheat Products**
By Prof. C. H. Bailey. (American Chemical Society Monograph Series, No. 96.) Pp. 332. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1944.) 6.50 dollars.

THE object of reviewing a book is to give readers some information on the author and his authority for writing on the particular subject, to indicate the scope of the book and to give an impartial evaluation of the value of the work. This is not a particularly difficult task in this case.

C. H. Bailey, professor of agricultural biochemistry in the University of Minnesota, is one of the foremost cereal chemists in the world. His work, often with a band of devoted students and postgraduate workers, is well known to all workers in that field. His contributions, both in quantity and quality, to cereal chemistry probably exceed those of any other worker. He was awarded the highest honour that can perhaps be given to a cereal chemist, namely, the Osborne Medal of the American Society of Cereal Chemists, in 1932. He has practical experience of book-writing in that he published in 1925 a book entitled "The Chemistry of Wheat Flour", which was No. 26 of the Monograph Series of the American Chemical Society, of which the present book is No. 96. Nobody, therefore, is better fitted to undertake the task of collecting together in book form the known facts on the constituents of wheat and its products. With characteristic painstaking thoroughness, Prof. Bailey has for years been working on a card index system to collect the necessary facts for the present book.

The book has a definitely restricted scope. It does not deal with the processing of wheat and its products, the chemistry of such processing such as the changes which occur in milling and bleaching, or in the making of bread or confectionery goods. It is hinted in the preface that a further book dealing with these and allied matters may be issued later. So far as it is possible to make such an arbitrary division, the present book is concerned with exactly what the title states, namely, the nature of the various constituents, such as the proteins in wheat and its products, the character of the starch, sugars, gums, lipids, minerals, pigments, etc., present, and particularly the vitamins which are now known to exist in the various portions of the grain. The vitamin chapter is typical of the whole book in that it gives a comprehensive account of practically all the important work which has been done, especially the recent work. What will be particularly appreciated is the fact that this chapter covers not only $B_1$ and its distribution in the grain, but also all the known facts with respect to the presence of riboflavin, nicotinic acid, pyridoxine, pantothenic acid and other vitamins in the whole grain, in various types of flour and in offal, including germ.

The book comprises sixteen chapters. Practically the first half, namely, up to p. 139, is concerned with the protein and other nitrogenous constituents. This part is particularly full, but contains much of the earlier work, now known to be of little value but which is presumably retained as of historical interest and to give the background for the more recent work. The book is not intended as a textbook for the various industries concerned. There is little general discussion and it consists essentially of a record of published scientific investigations. It will therefore be of particular value to future research workers. The book is well balanced and there are relatively few omissions to work that matters. The comprehensiveness of the book, although only of 332 pages, is seen from the fact that there are approximately eight hundred names in the authors' index, and the references to published papers approach 2,000. The book appears to be singularly free from errors and misprints, although it was observed that in Table 112 the last column should presumably have been mgm. per 100 gm. and not mgm. per lb. Incidentally, the variety of ways in which vitamin results are recorded, such as μgm./gm., mgm./100 gm., mgm./lb., etc., are always confusing, and it is convenient to have the relationship table given on p. 282 of the book.

The book not only fulfils a real want but also fulfils that want well. There is a scarcity of good books on the chemistry of wheat and its products, and this is true of any language. We have no hesitation in recommending this book to all advanced workers in this field—in fact, they cannot afford to be without it. D. W. KENT-JONES.

## Endocrine Man

A Study in the Surgery of Sex. By Dr. L. R. Broster. Pp. xi+144. (London: William Heinemann (Medical Books), Ltd., 1944.) 12*s.* 6*d.* net.

IT is impossible to review this book in the space available. It is full of ideas, records of experimental work and stimulating discussion. Every page of it counts. The author is a surgeon at the Charing Cross Hospital, and his broad thesis is a discussion of the origin and evolution of what he calls the instinctive tripod, namely, self-preservation, growth and sex, all of which are classified as instincts. The chapter leading to his discussion of instinct is a remarkable summing up of the development of animals. Like the final chapter on the nature of man, it reveals the author's wide knowledge and outlook.

The chapters on the evolution of species, on the physiology of the autonomic nervous system and on the functional evolution of the endocrine system are no less valuable. The last-named chapter introduces the author's study of virilism, feminism, intersexuality and other more obscure conditions due to disorders of the adrenal, the pituitary and the genital glands, which he has been conducting with his collaborators at the Charing Cross Hospital for the last fifteen years. The book reveals some of the remarkable results which have been achieved by the surgical treatment of these disorders and discusses their biological significance. The quality and trend of this discussion may be gathered from the author's suggestion, based upon his experience and clinical observation, that, whatever the genetic (chromosomal) constitution may be, this may be overridden by hormonal influences.

In his last chapter the author suggests that slight adaptations resulting from nervous and endocrine control (he has already discussed the interplay between hormones and the functions of the brain) could be "inscribed in the framework of the germ cells". This view visualizes the vital role of the endocrine system in the integration of development and also suggests that "variable factors may be introduced into the germ plasm through its hormones to account for influences which, on the whole, have consistently led to the progress of mankind". Sir Peter Chalmers Mitchell contributes an interesting foreword and there is a valuable bibliography. Everyone will hope that the work of this team, interrupted by surgical war service, will be resumed as soon as possible.

G. LAPAGE.

## Human Reproduction and Venereal Disease

By Dr. John Drew. Pp. 124. (London: Faber and Faber, Ltd., 1944.) 3*s.* 6*d.* net.

THIS layman's guide to the venereal diseases is wider in scope than the title suggests. It covers human anatomy, the venereal diseases and their treatment, their relation to sterility and their sociological implications. The descriptions of diseases are accurate, but as the author has gone to so much trouble to give the medical terms for the lesions he describes it would have been wiser to avoid all possibility of misinterpretation in the case of "condylomata" and have called them "condylomata lata". Many people have condylomata but only some are also syphilitic. Some purists might quibble at the guides to pronunciation given for treponema (treppon-nee-mar) and gumma (gum-mar).

A book for laymen is scarcely the place to indulge in discussions about criteria of cure in syphilis. Even if biological cure cannot be attained, clinical cure is possible in nearly every case of early syphilis if the patient will co-operate, and this is all that it is necessary to say. A more hopeful note could have been sounded on the length of treatment for syphilis in these days when intensive treatment is widely used and penicillin is just over the horizon.

## Sheffield Burns

By Dr. W. H. Hatfield. Pp. 213. (Sheffield: J. W. Northend, Ltd., 1943.) 7*s.* 6*d.*

SHORTLY before his unexpected death, Dr. Hatfield, whose name is closely associated with the development of special steels, had completed some reflexions on people and things, inspired by the sight of the great conflagration in Sheffield during the air raids of 1940. Dr. Hatfield was a devoted son of Sheffield, and his aim in writing was to help in its restoration. The little book contains reminiscences of the author's contacts with scientific men and other notable people at home and abroad, brief accounts of visits to industrial centres in other countries, and expressions of personal opinion on matters of public interest. His views on economic questions, based on experience in large-scale industry, lean strongly to the side of private enterprise, while his remarks on scientific and industrial research and its organization gain weight from his own marked success in stimulating co-operative research in the iron and steel industry, and from his earnest advocacy of a similar policy for industry in general. Any profits from the sale of the little book are to be devoted to St. Dunstan's.

## The Statesman's Year Book

Statistical and Historical Annual of the States of the World for the Year 1944. Edited by Dr. M. Epstein. Eighty-first annual publication, revised after Official Returns. Pp. xxxvii+1484. (London: Macmillan and Co., Ltd., 1944.) 30*s.* net.

IN spite of current difficulties, the new issue of this valuable reference volume maintains its scope and size. Revision of statistics has been difficult and for many States impossible, but the latest available are given. For many parts of the British Commonwealth and the United States figures are of a recent year. The section on the armed forces of the United States has been extended. Other additions include a short account of the British Council and its aims, the Middle East Supply Centre, and, under Australia, an account of the Australian Capital Territory. The introductory tables of comparative production of various commodities have had to be omitted, but there is still a section on the League of Nations. A coloured map shows the extent and boundaries of Poland at various periods in the history of that State. The useful book-lists for each State have been fully revised.

## Brompton Hospital Reports

A Collection of Papers recently published from the Hospital. Vol. 12, 1943. Pp. vii+163. (London: Brompton Hospital, 1944.) 8*s.* net.

THE papers in this volume are reprints of recent work by members of the Brompton Hospital staff. Most are concerned with diseases of the chest. In an interesting statistical survey on "The Health of the Doctor", Dr. A. Hope Gosse challenges the title of 'the doctor's disease' often given to coronary thrombosis.

# METEORITES OR SPRINGS AS GEOLOGICAL AGENTS?

By DR. E. B. BAILEY, F.R.S.
Geological Survey of Great Britain

DOUGLAS JOHNSON'S recent death is mourned by a wide circle of friends and admirers on both sides of the Atlantic. Johnson delighted in interpretation of scenery and showed to equal advantage in choice of subject, plan of attack and clarity of exposition. In his latest monograph[1], which includes forty-six illustrations, mostly air-photographs, he dealt with a problematical erosion form represented by tens of thousands of parallel, oval, marshy hollows pitting the coastal plain of America. The area affected measures some 25,000 square miles, and ranges through South Carolina into neighbouring States. Here marshes of any shape are commonly called 'bays', perhaps, it has been suggested, because bay trees flourish in them. This local practice accounts for the title selected by Johnson for his book, "The Origin of the Carolina Bays". Johnson alternatively speaks of the oval hollows as craters. They are shallow basins, measuring anything from a few hundred feet up to four miles in length, and averaging about 50 ft. in depth, when allowance is made for partial infilling with peaty silt. Usually they are more or less completely encompassed with white sandy rims.

The parallel oval hollows are patchily distributed over a terraced plain which, eighty miles inland, rises to a maximum elevation of 300 ft. above sea-level. According to C. W. Cooke's account, the surface consists of a veneer of Pleistocene marine sands, sandy loams and clays, often less than 50 ft. thick. These rest unconformably upon various Tertiary and Upper Cretaceous formations, which effectively conceal a depressed floor of ancient crystallines. The oldest of the Cretaceous formations, the Tuscaloosa, is still in the condition of sand with interstratified clay. Along with several of the later formations, it carries abundant water, sometimes under artesian head. True artesian, overflowing wells are a commonplace throughout the region.

The peculiar oval form characteristic of so many of the Carolina hollows was first brought to the notice of scientific men in 1895 by L. C. Glenn. He regarded it as produced under coastal or sea-bottom conditions; but I think we must follow Johnson in attributing the ovals definitely to the post-emersion history of the plain. Glenn's descriptions attracted little attention until reinforced by aerial photographs, taken for forestry and other purposes. Then in 1933 came a dramatic paper by F. A. Melton and W. Schriever, claiming the oval hollows as scars of a prodigious shower of meteorites. The main basis of this hypothesis was the amazing tendency to parallelism exhibited by the ovals of any particular district.

Melton and Schriever's appeal to heaven met with a mixed reception. Cooke and Johnson were early opponents. In the volume under review, Johnson devotes four chapters to its criticism, from which I select a few points which seem to justify his unbelief: (1) the parallelism of the ovals is not regional, for near the border of North and South Carolina the general orientation is south-east, whereas near that of South Carolina and Georgia it is south-south-east—here in passing it may be remarked that in the former locality the ovals are mostly elliptical, and in the latter egg-shaped, with the small end pointing south-south-east; (2) if the hollows were meteorite scars, they would almost certainly have to be attributed to meteorite explosions; but an explosion is necessarily quasi-instantaneous and therefore has a strong tendency to give a circular, not an elongated crater; (3) anyhow, the rims consist of clean, washed sand, in contrast with the loamy sand of the plain upon which they rest—they cannot be interpreted as made of plain sand thrown out by explosion; (4) no fragments of meteorites have been found in much the greater part of the region—though we must remember that no fragments of the great Siberian meteorite have been recovered and also that iron is soluble; (5) magnetometer search for buried meteorites has given unpromising results.

Cooke and Johnson, in attacking the meteorite hypothesis, agreed that every oval hollow held a lake during some formative stage of its career, and that the associated sand rim is in a sense a beach coupled with dunes. The rims are conspicuous in air photographs, because they carry very little vegetation. On the other hand, they seldom rise more than 10 ft. above the plain, though occasionally spreading outwards for several hundred feet across it. They are not infrequently multiple. So far, I think that Cooke and Johnson are correct; but, when they go on to claim wind-operated water as a main shaping agent of the ovals, I think they are mistaken. At first both authors invoked a longitudinal wind to account for the elongation and parallelism of the ovals; but eventually they abandoned this particular conception. Here in outline are their subsequent strongly divergent views.

Cooke thinks that a steady wind blowing across any lake with yielding shores tends to set up a rotating current, and that this current would assume a circular path if only the earth were standing still. Under existing conditions of earth rotation, he claims that the current tends to become elliptical with its major axis directed north-west in the northern hemisphere. He further considers that the ideal resultant ellipse would have an axial ratio equal to the sine of the latitude; and he quotes a number of Carolina ovals conforming with this quantitative plan. I confess that after reading what Johnson has to say on this subject, and Cooke's own recent reply[2], I think the latter's argument is faulty.

Johnson devoted the last seven chapters of his book to what he called his "hypothesis of complex origin". In it, wind-driven currents and waves are given much less importance than in his previous hypothesis. In fact he was prepared to hand over the making of the hollows, their elongation, parallelism and the rough shaping of their oval form to springs controlled by underground conditions. The only essential service he asked of the wind was to smoothe the shores of the ovals by removing headlands and, embanking bays, with concurrent development of sandy rims. Even so, I think it possible to demonstrate that he trusted too much to the wind and too little to the springs.

I think that Johnson paid too little attention to the phenomena of intersecting ovals as illustrated, for example, in the figure here reproduced. Surely one is bound to ask how, on Johnson's hypothesis, was the wind persuaded to leave intact cuspate headlands at the points of intersection of two contiguous ovals; and how was it educated to connect such headlands with a bar of drifted sand, which, continuing faithfully the curvature of the shore of one oval, utterly

disregarded the contour of the other. Clearly the formation of oval basin and oval rim was an operation one and indivisible. The rim sand can be called a beach if so desired, but it was thrown out, not drifted along. In this important matter, Melton and Schriever seem to me to have come nearer the truth than Johnson. I do not mean to say that the phenomena of intersecting ovals rehabilitate the meteorite hypothesis, but I do think that they entail a more violent use of Johnson's springs than their author thought necessary or at all desirable.

Before leaving the subject of wind, I may say that Johnson has convinced me that wind has often co-operated in important matters of detail. I refer especially to a frequent slight exaggeration of the curvature of the ovals on their eastern sides and a corresponding marked accentuation of rim development in the same direction. It looks to me as if, when the hollows were formed by spring action, a westerly wind was usually blowing.

INDEX MOSAIC OF AERIAL PHOTOGRAPHS COVERING PART OF BLADEN CO., NORTH CAROLINA. NOTE ELLIPTICAL FORM AND SOUTH-EAST TREND OF THE DARK MARSHES KNOWN AS 'BAYS'. NORTH IS AT TOP. THE LARGE 'BAY' SOUTH-EAST OF CENTRE IS THREE MILES IN LENGTH. FROM FIG. 29 OF "THE ORIGIN OF THE CAROLINA BAYS".

Let us now turn to consider Johnson's spring hypothesis. One of his main ideas is the eruption of an artesian spring through impermeable cover. This would result underground in a water-rise, the inverse of a waterfall; and Johnson thought that a water-rise must have a strong tendency to migrate up-dip through backward erosion of the impermeable obstacle that it has breached. Accordingly, he held that artesian springs at the surface in any particular locality will migrate parallel with one another in a direction contrary to that of the dip of the underground strata. Continuing, he pointed out that a stationary spring may be expected to develop a circular pool, if it emerges through a superficial deposit of loamy sand, because of removal of continually agitated material, in solution if soluble, or in suspension if of a clayey nature. Such a process would leave a residue of quartzose sand to be eventually collected together to form a rim—here it may be noticed that the rim sand outside any Carolina hollow is always of much less volume than the hollow itself. Johnson also considered that a circular pool thus formed would expand considerably through slumping of the loamy sand forming its banks. Finally, returning to his hypothetical migrating springs, he argued that at the surface they would act in all particulars like stationary springs, except that they would give elliptical instead of circular pools.

I consider that we must modify Johnson's spring hypothesis in certain particulars before we can adopt it. There are two main reasons: (1) it is extremely doubtful whether artesian springs show any marked tendency to migrate up-dip; (2) Johnson derives his oval hollows through intersection of successive circular hollows. Let us examine this last point. We have seen that intersection of oval hollows is characterized by cuspate headlands often connected by a well-developed rim. Intersection of circular hollows should be similarly advertised if it had really taken place.

Personally I accept Johnson's conception of spring action with linear application determined by some structure in an impermeable layer through which the water has risen; but I think that appearances prove that the spring of our hypothesis made a simultaneous attack all along the line, instead of starting at one end and gradually migrating to the other. This clearly indicates guidance by joints in the impermeable layer rather than by dip. Dip can, however, probably be retained as a factor of local importance. In some districts, as already stated, the ovals are egg-shaped. This would be expected if the top of the impermeable, jointed layer has a fairly pronounced dip in the direction of an opened joint that gave passage to rising water. It is clear that the water, issuing nearer the surface at one end of the joint than

at the other, would produce an asymmetrical result. I imagine the pool would narrow in the direction of dip.

It will be noticed that I have proposed a drastic reduction in Johnson's time-table. This involves a greatly increased call upon water supply, measured in gallons per hour. A little further thought shows, however, that the supply was maintained only for a very short period. The water which made a hollow with rim complete cannot have continued to flow on anything like the same scale after it had done this work. Otherwise it would have cut an escape channel of dimensions comparable with those of the spring pool. Many of the depressions do have escape channels, but these are on a scale commensurate with that of certain artesian springs which are occasionally to be identified in the marshy bottoms.

The sudden cessation of the springs of our modified hypothesis removes them at once from the artesian category. Such transient springs must depend on load pressure for their activation. When an earthquake shakes an alluvial district it generally leads to discharge of sand and water from numberless craterlets. I imagine the cause must be a repacking of wet sand into patches, some of compacted sand comparatively waterless, others of loose sand lubricated with water and incapable of sustaining load pressure unless furnished with outside support. As a result, almost immediately after an earthquake has occurred in a suitable locality, sandy water spurts up a few feet into the air from craterlets and fissures, and soon ceases to flow, seldom persisting for more than a few hours. I am inclined to think that some such subterranean re-arrangement of sand and water was responsible for delivery of water at the surface during the formation of the Carolina hollows. It would account among other things for the frequency with which activity shifted from one site to another. An area of underground sand, once repacked with extrusion of water, would likely remain stable in later recurrences of stress.

There are striking resemblances connecting the Carolina region with familiar fields of earthquake hydro-eruption, such as those of the Mississippi (New Madrid), 1811–12, Assam, 1897, and Bihar-Nepal, 1934. There are equally striking contrasts. I hesitate to suggest that the Carolina hollows are earthquake craters, but I do hold that the idea is worth serious consideration. Among resemblances is the vast area over which sanding from numberless craterlets may occur after an earthquake. J. A. Dunn, J. B. Auden and A. M. N. Ghosh have found this effect scattered throughout 18,000 square miles in connexion with the Bihar-Nepal earthquake[3]. The differences concern in part the relatively small size of known earthquake craterlets. An elliptical blow-hole at Muzaffarpur, measuring 25 ft. by 10 ft., is quoted as a large example (*loc. cit.*, p. 35). The craterlets seem to make up in number for what they lack in measurement. "In places the surface was riddled with sand vents, sometimes so completely that small areas up to an acre or so in extent, might be compared with boiling porridge. . . . The universality of the sand in some places, and the closeness of the vents, suggest no great depth for its origin, since the greater the depth of the channels leading up to the vents the more localised and separated would they probably be" (*loc. cit.*, pp. 34, 36).

Perhaps a more serious difficulty presents itself in regard to regional, as opposed to local, parallelism. Earthquake craterlets are often strung along fissures (furnishing possible composite homologues with individual Carolina ovals), and earthquake fissures may themselves be opened up into craters. This introduces a pronounced element of local parallelism, for earthquake fissures tend to be parallel with their contemporaries and predecessors in any small district. Recurrence of parallel fissuring is well illustrated in Charles Lyell's account of how the inhabitants of the New Madrid area, which shook again and again during a period of several months in 1811–12, felled trees at right angles to the fissure direction to serve as bridge-refuges for use should later tremors give warning of approaching trouble. On the other hand, many earthquake fissures are orientated on a strictly local basis parallel to topographical features, whether negative as in the case of the banks of a river or pond, or positive as in the case of a road embankment or heavy building. In the Bihar-Nepal earthquake, fissures on flat country "rarely showed any constancy in direction; more generally they occurred as an irregular network" (*loc. cit.*, p. 32). M. L. Fuller, however, found matters otherwise in the New Madrid area[4]. He recognized, indeed, that many fissures had been controlled by topography, but added: "the second class, or the simple fissures of the sandblow areas seem to have a tendency toward a definite arrangement, along northeast-southwest lines (averaging N. 30° E.), although where the blows are scattered the arrangement is not always very apparent. The fissures of the sand sloughs are in general parallel to the depressions and are even more commonly aligned in northeast-southwest directions". One must remember also a suggestion made long ago, and never so far as I know refuted, that much of the parallel jointing of rocks in general is an earthquake phenomenon. It is to be hoped that the next great ejective earthquake will be followed by a careful air survey.

# PAVLOV'S WORK ON HIGHER NERVOUS ACTIVITY AND ITS DEVELOPMENT IN THE U.S.S.R.

By FREDA M. THOMAS
London School of Medicine for Women

NEWS has recently been received from the U.S.S.R. of the work of Prof. Maria Petrova, who has been awarded the Order of the Red Banner of Labour by the Soviet Government for her work on problems connected with higher nervous activity*. Since she joined Pavlov's laboratory at the Institute of Experimental Medicine in Leningrad in 1910, she has carried out countless experiments in this field and even refused to interrupt her experiments during the recent siege. Prof. Petrova is typical of the majority of Pavlov's pupils, who, after his death in 1936 at the age of eighty-six, determined to carry on his work, and in the words of Prof. Frolov "to occupy

* All the recent information in this article has been obtained from cables sent by the Academy of Sciences of the U.S.S.R. For the use of this material I am greatly indebted to Sir John Russell, of the Anglo-Soviet Scientific Collaboration Committee of the British Council, and the Ministry of Information.

themselves with organizing new experiments so that by their collective labour the breach in their ranks might be made good"[1].

Before proceeding to the subject-matter of the cables concerning Prof. Petrova's work, it would seem fitting to give some account of the magnificent work of her master, Pavlov, the fundamental value of which, as was pointed out in one of his obituary notices[2], is shown by the fact that so much of it is now regarded as common knowledge.

Pavlov graduated from the Military Medical Academy in St. Petersburg in 1879 and worked as assistant to Tsion, the discoverer of the depressor nerve, until in 1884 he went to Leipzig to work under Ludwig, from whom he probably acquired some of his precision in observation. He then worked under Heidenhain at Breslau, absorbing some of his enthusiasm for science, and developed the technique of permanent fistulæ and isolation of parts of the gastro-intestinal tract. He returned to St. Petersburg in 1886 and was soon put in charge of Botkin's experimental laboratory, where he showed his talent for the organization of research. In 1890 he was made professor of pharmacology in the Military Medical Academy and five years later succeeded to the chair in physiology.

Throughout his work, Pavlov took pains to have conditions as normal as possible: for example, when working on the circulation, he endeavoured to accustom the dog to the insertion of a cannula, and in the construction of the 'Pavlov pouch', part of the stomach was isolated with negligible interference with the nerve supply. He emphasized the importance of surgery in experimental research, and of having healthy, well-cared-for animals, which he treated as human patients with regard to anæsthesia, asepsis, narcosis and care after operation. It was probably as a result of his work that scepticism arose as to the applicability to medical practice of results obtained from narcotized or decapitated animals. In 1891 he organized the surgical department of the physiology laboratory in the new Institute of Experimental Medicine, the first of its kind in the world, founded and financed by the Prince of Oldenburg, and it was here that he carried out most of his work on digestion, for which he received the Nobel Prize for Physiology and Medicine for 1904[3]. As Anrep pointed out in an obituary notice[4], most of the facts relating to digestion as it is now known either had their origin, or were established, in Pavlov's laboratory.

By 1906, Pavlov had transferred his investigations to the brain, but he used similar methods, still striving towards normality, carefully isolating his variables and keeping all other conditions constant. He focused his attention on the correlation between external phenomena and the reactions of the organism as a whole, and he followed the lead of Claude Bernard in regarding the animal body as an unstable system which constantly maintains its equilibrium with its environment; and for the maintenance of this equilibrium he was struck by the importance of conditioned reflexes.

As a result of his investigations into the so-called psychic flow of some of the digestive juices, Pavlov had become convinced of the futility of subjective methods of inquiry; he objected to psychologists applying their own experiences to the brain of the dog and asked: "to understand these phenomena, are we obliged to enter into the inner state of the animal, to fancy his feelings and wishes as based on our own?" His sham feeding experiments had shown that simultaneous excitation of organs of sight, hearing, taste or smell influenced the activity of gastric glands, and thus the idea of a complex subjective sensation was transformed into what he described as "a concrete factor of the physiological laboratory".

By gradually establishing conditioned reflexes through the simultaneous application of an 'essential' and an 'unessential' stimulus, Pavlov was able to substitute a more nearly normal animal for the study of behaviour than could be obtained by acute experiments involving artificial stimulation of different parts of the brain; and in Pavlov's life-time their study had made many important contributions to an understanding of the nature of sleep, neuroses and temperament.

The response selected for study was the secretion of saliva in dogs of which the salivary duct had been brought to the exterior of the cheek so that the quantity of saliva secreted in a given time could be measured. Pavlov pointed out that this choice, although originally accidental, satisfied the fundamental demand in scientific investigation for beginning with the simplest case; it also had the advantage of being easier to assess and less likely to cause complications than a motor response. The 'essential' stimulus was the giving of food, but the reflex could be conditioned to an infinite variety of stimuli such as the ticking of a metronome, the flashing of an electric lamp, the appearance of certain figures with varying intensities of illumination, a trumpet or telephone, rhythmic contact of blunt or sharp instruments with the skin, or warming and cooling particular parts of it. By these means, therefore, it was possible to learn much about sense organs and powers of discrimination, such as limits of audibility, distinction between metronome speeds, musical intervals and combinations of musical sounds, as well as much about the general and localized functions of the cortex.

Pavlov showed that association was a simple analysis followed by synthesis, then generalization, and finally analogy; since a dog could not only differentiate an interval in one part of the musical scale but also would respond to all such intervals in other parts of the scale. The fact that conditioned reflexes were lost if the cortex was removed confirmed earlier findings by Goltz that decorticated dogs showed no initiative, would only eat if food was placed in their mouths, and generally lacked the power to adapt themselves to changes in their environment. Pavlov and his workers increased the knowledge of the map of the cortex by establishing certain conditioned reflexes and finding whether or not they persisted after removal of different parts of the cortex, although it was shown that in time compensation occurred and some parts of the cortex could replace others.

Pavlov paid great attention to the welfare of his experimental animals, and minimized all experimental errors by mechanical appliances and by isolating his animals so that even the observer and operator were in an adjoining room. He was at one time in charge of three laboratories and sometimes had more than sixty people each working on a different problem, but he himself remembered the details of every investigation. His recognition of the value of the division of labour led to the organization of research teams, of which there are now so many in the U.S.S.R., the United States and Great Britain.

Pavlov's new laboratory at the Institute of Experimental Medicine in Leningrad was built with

funds from the Ledenzov Society for the Advancement of Experimental Sciences and their Application.

At Koltushy, now Pavlovo, a village twenty miles north of Leningrad, the Soviet Government built for Pavlov an establishment which combined laboratories with a rest-home for scientific workers. The buildings bore the inscription: "Experimental Genetics of the Higher Nervous Activity" and on the tower was Pavlov's watchword: "Observation and again Observation". Each animal had a separate dwelling-place and there was a hospital, exercising hall and maternity centre for the bitches. His two chimpanzees, Rafael and Rose, presented by Prof. Voronov, also had their own buildings.

Early in his study of conditioned reflexes, Pavlov showed that stimulation of the cortex produced excitation. This first spread over a large area and was described as irradiation, and would be followed by concentration, which would be accompanied by inhibition such as occurs where antagonizing muscles are concerned. He was engaged on this work when Maria Petrova, who had just graduated from the newly opened Women's Medical Institute in St. Petersburg, joined his laboratory in 1910. Her thesis for a doctor's degree in 1912 was entitled "Processes of Irradiation and Excitation in the Cortex of the Brain", and together with Krasnogorsky she performed many experiments on excitation and inhibition. She also studied sleep, which, as the result of their experiments, Pavlov was led to regard as generalized inhibition extending to some sub-cortical areas, just as he regarded hypnosis as localized or partial inhibition. She later participated in the work on experimental neuroses which were produced by causing interference between the two opposing processes, excitation and inhibition, leading to rupture or breakdown of the cortical mechanism. They studied animals with different types of nervous systems; and by producing experimental neuroses in dogs, in some of which inhibition predominated, whereas in others excitation was most pronounced, obtained conditions resembling easily recognizable psychical disorders in man. They made extensive use of caffein and bromides in carefully graded doses in the investigation and subsequent cure of these conditions[5,6], and Prof. Petrova recently received the Pavlov prize for her book on this subject. During the last years of Pavlov's life, he became increasingly interested in the applications of his work to psychiatry, and both Krasnogorsky and Petrova devoted much time to these problems. Although Pavlov stressed the importance of the objective approach to psychology, he pointed out the help which physiology might derive from the study of clinical cases. He therefore made use of psychiatric data and visited clinics and talked to the patients. He maintained a lively interest in therapeutic measures, and in his last year initiated the treatment of schizophrenia by prolonged sleep.

Petrova has also continued the work which Pavlov began on the relation between the endocrine organs and higher nervous activity. For example, they found it difficult to establish conditioned reflexes in thyroidectomized or senile dogs, and relatively easy to produce experimental neuroses in castrated dogs. Pavlov also showed the influence of the cortex on some endocrine activity; for example, a conditioned reflex was repeatedly reinforced by administration of thyroid extract; then, when the extract was no longer given, an increase in metabolic rate was obtained in response to the secondary stimulus.

In a cable from Moscow, Prof. Krikor Kekcheyov records that after Pavlov's death in 1936, Petrova joined Pavlov's oldest colleague and successor, Leon Orbeli, at the Institute of Physiology of the Academy of Sciences of the U.S.S.R. Her work there has included a study of the part played by the nervous system in the origin of malignant tumours, the production of experimental neuroses by the use of strong irritants of the nervous system, and in 1943 she established the connexion between the severity of disorders of higher nervous activity and the development of eczema and various tumours.

A cable from Petrova herself says that she has never left Leningrad for an hour since the War began as she knew that her great master Pavlov would not have done so. She gives a vivid description of conditions in that city and makes many bitter comments on the tyranny of the German invaders. During the siege, which lasted nine hundred days, she refused to leave the city in spite of being repeatedly urged to do so, and she says she found satisfaction in working sixteen hours a day and wrote twelve scientific papers, of which she mentions the following: "Conditioned Reflexes as a Method of Throwing Light on Mental Traumata and the Origin of Various New Processes, in particular Cancer", "Influence of Fear-inducing Factors of Military Operations on Higher Nervous Activity in Dogs with Differing Types of Nervous System", "Causes of Old Age and Prophylactic Measures against Premature Old Age". As a specialist in higher nervous activity, she was able to observe the psychology of her fellow citizens and records with pride that the harder life became in the besieged city, and the more savage grew the German persecution in the form of hunger and bombardment, the more clearly did she perceive the people's firmness, unbending will, 'comradeliness' and habit of mutual assistance. The Pavlov Institute of Physiology was among the many important buildings damaged by bombs and shells, but in spite of these attacks, research was not interrupted, and scientific workers in Leningrad also spared no effort to defend their city. For months the daily ration of the people was 125 gm. of bread containing only 50 per cent flour.

Pavlov considered that a certain degree of discomfort is good for a fertile mind, and that a shortage in apparatus and material trains resourcefulness. It is interesting to compare Prof. Petrova's description of work under the conditions of this War with an account of one of Pavlov's assistants of their work during the War of 1914 and the Revolution. "It was often very difficult to get to the laboratory at all, because, besides other things, there was often shooting and fighting in the streets"; but Pavlov was generally present even if he was the only one, and he severely criticized any late-comer if there was an experiment to be done. He continued his work in the laboratory on short winter days by the light of wood torches and used a kerosene lamp for lectures, in which there was no break either at the Military Medical Academy or the Institute of Physiology.

Pavlov was convinced that only science could lead the human race to a bright future free from war, revolution and catastrophe, and at the opening of the fifteenth Physiological Conference in Leningrad in 1935 he said, "War is by its nature a bestial method for solving the difficulties of life, a method unworthy of the human mind with its immeasurable resources", and he placed great faith in the efforts of the Soviet Government with Stalin at its head in its struggle

for world peace. In that year Cannon remarked that the outcome of the efforts, which were being encouraged by the Soviet Government, to use Pavlov's methods to condition the cortex in new ways and thereby to bring about a reformation of conduct would be watched with supreme interest[7]. Pavlov himself, in a letter to young scientific workers shortly before his death, said: "It is a matter of honour for the youth, as well as for all of us, to justify those great hopes which our fatherland places in science".

Pavlov has been accused of over-simplifying a remarkably complex subject, but his theories have provided useful working hypotheses and they have stimulated effort and increased the extent of careful experiments by those who agreed as well as those who disagreed with his views. He himself considered theories as worth while only for finding new lines of attack and accumulating facts. He stressed the importance of repeated tests to establish the reproducibility of results, and he shrank from making general conclusions. His work affords a striking example of true scientific method, and it is satisfactory to learn that his colleagues in the U.S.S.R. have been able to develop it still further in spite of the difficulties of war conditions.

# THE ROYAL NAVAL SCIENTIFIC SERVICE

DURING the War of 1914–18 technical progress went ahead, as has again happened in this War, at a vastly increased rate in all the Services. In order to compete with the demands for new weapons and counter-measures, the help of numbers of men of science from the universities and technical men from private firms was enlisted, and these men were employed in naval establishments all over Great Britain. They were employed very largely on new methods for detecting and destroying enemy submarines and on developments in radio, new types of mines, methods of mine-sweeping, work on underwater explosions, torpedoes and navigational devices and the like. The work of these men was of immeasurable value to the Navy, and directly after the War the Admiralty decided, as a result of its experiences during the War, to set up a civilian scientific research department under a civilian Director of Scientific Research. The first Director of Scientific Research in the Admiralty was appointed at the beginning of 1919. He was Sir Frank Smith, who had himself during the War been largely concerned with the development of a type of magnetic mine which can be regarded as a forerunner of the German magnetic mine, which was used against Britain during this War. The Admiralty also set up its own research laboratory under the Director of Scientific Research for the conduct of the more fundamental types of scientific investigation.

Gradually during the years of peace the civilian scientific and technical staffs employed in the Naval Establishments were put under the general administrative control of the Director of Scientific Research, instead of being separately administered as they had been during the War. These staffs were embodied in the Admiralty Scientific, Technical and Chemical Pools, and this arrangement ensured a greater measure of uniformity in the conditions of service in the different establishments, and among people engaged on different types of research and development work, and it also ensured common methods of selection and entry into the scientific, technical and chemical services of the Admiralty. During the years of peace also, the Air Ministry and War Office set up civilian scientific research departments, which were modelled very largely on the Admiralty organization.

The steps outlined above were steps in the right direction, but there is no doubt that the Navy, and indeed the other Services, suffered a good deal because the conditions of service of the civilian technical staffs were not such as could attract the best types of men from the universities and other sources upon which the Admiralty depended. Apart from pay and promotion prospects, the lack of opportunity for publication and loss of outside recognition, as well as rather rigid research programmes, were against the Services in their need for first-rate men.

Some of the men of science and engineers who entered the Admiralty Service in the War of 1914–18 are still there, and it is to the work of these men and to those who entered the Service during the years of peace that we owe our state of preparedness, such as it was, to meet the onslaught of Germany. During the present War, the permanent Admiralty staffs have again been greatly strengthened in numbers and in quality by men of science and engineers drawn again from the universities, research institutions, private firms and other sources. The great advances which have been made in almost every form of technical weapon and in counter-measures are largely due to this body of people, working in the closest daily association with industry and outside men of science and engineers, including those of the United States and the Dominions, with the naval technical departments, and with the divisions of the naval staff, who decide in broad outline what are the Service needs.

The announcement of the formation of the Royal Naval Scientific Service is an indication that the Admiralty, having been the first Service department to take the then epoch-making step of setting up a civilian research department within its organization, still recognizes the vital importance of taking yet further steps to ensure that scientific research and technical development for the Navy shall not lag behind during the future years of peace.

The Admiralty desires to see the closest co-operation between the men of science and the uniformed officers of the Service, and it proposes giving fuller opportunities than have hitherto been regularly possible for civilians to become thoroughly versed in the ways and the needs of the Service. Further, the civilians will, by virtue of the arrangements which will be made for obtaining sea training and experience, come to feel that they are more than ever before an integral part of the Navy. The Fleet Order shows also that the Director of Scientific Research, as head of the Royal Naval Scientific Service, will have greater freedom than hitherto in arranging for transfers of staff between establishments, so that the outlook of the technical men will become broader and more enlightened than it is apt to be if men of science and engineers specialize too long or too early in

particular aspects of Naval warfare. The reference to conditions of service including pay and prospects of promotion is vague, but it must be accepted at present as an earnest of the good intentions of the Admiralty.

The Admiralty and Government policy towards research in post-war years aims at giving research and research workers—in the broadest sense—recognition and status which they have hitherto lacked in Great Britain. It is also hoped that the R.N.S.S. will be accounted an honourable career for men whose leanings are towards science and the sea; that prospects offered by the R.N.S.S. will attract men of the highest calibre to devote their minds and their lives to solving the great problems which lie ahead of the Navy; that, though the Government service cannot generally offer monetary rewards comparable with those of the highest walks of industry, yet the other advantages of a Naval technical career will offset the possible financial disadvantage; that the Admiralty will be enabled to keep after the War some of the brilliant men who are serving it temporarily now; that there will be greater freedom for individual research workers to follow up lines of investigation for which they are personally fitted, and that the Government will not be so much inclined to look for quick returns.

# OBITUARIES

## Sir Arthur Smith Woodward, F.R.S.

SIR ARTHUR SMITH WOODWARD, lately keeper of the Department of Geology, British Museum (Natural History), died on September 2 at the age of eighty.

Sir Arthur was a great student of vertebrate palæontology, the widest in his work and knowledge of his time. When he left Owens College, Manchester, as a very young man to take a post in the Museum, he recognized that the work of R. H. Traquair on palæozoic fish had introduced a new standard of investigation and a new outlook, and immediately applied them to the study of later fishes. He travelled extensively so that he saw nearly all the original materials in the world, and his extraordinary memory enabled him to recall immediately anything which could throw light on the fossils on which he was actually working. Thus his catalogue of the fossil fishes in the British Museum marks an epoch in the study of such things. It was the first completely general detailed work since Agassiz's "Poissons Fossiles" and it has had no successor, so that it remains the point of departure from which all subsequent work has proceeded. To him came collections of fossil fish from every part of the world, to be in turn described, placed in their position in the classification, and their geological horizon determined. Thus he became known to palæontologists everywhere, and was ultimately a foreign member of some twenty scientific societies.

But Sir Arthur's interests extended far beyond fish. He wrote on fossil Amphibia, reptiles, birds and mammals, doing something of interest in each of those groups, and finally he described the Piltdown man, actually himself finding part of the material at Piltdown.

His quality was well illustrated by the text-book of vertebrate palæontology which he published in 1900. This differed in every way from those which then existed; it was accurate, it dealt only with forms which were important morphologically, it was based entirely on materials which the author had seen, and it was readable.

When Sir Arthur entered the Museum the collections of fossil vertebrates, though large, had not been brought together on any considered plan. Under his influence and guidance they were expanded so that every important fauna in the world was represented, often by most admirable materials. But all were bought, sometimes after they had been sought for many years. Although Smith Woodward himself made a collection of fossil mammals at Pikermi, and Andrews explored the Fayum, no expedition was ever sent out at Museum expense; in consequence, during the past thirty years many foreign museums have exploited fossil faunas which are now inadequately or not at all represented in London.

But Smith Woodward always felt that he was a public servant. Everyone, British or foreign, had access to all the fossils in his charge, and was allowed to describe anything he wished. Thus the Museum gained because its collections were worked over by men from many countries, and palæontology gained because specialists could use its materials, as if they belonged to their own institutions.

So Smith Woodward became known and admired by the whole body of palæontologists, occupying a place no one can now fill, and leaving behind a great mass of admirable work, part of the foundation of modern palæontology. D. M. S. WATSON.

## Prof. S. P. Mercer, O.B.E.

THROUGH the death of Prof. Stephen Pascal Mercer which occurred on August 18 at the comparatively early age of fifty-three, Northern Ireland has lost an outstanding figure in the field of agricultural education and one who played a prominent part in laying a sound foundation for the Faculty of Agriculture of Queen's University, Belfast.

S. P. Mercer (S.P.M., as he was known to so many of us) was a Staffordshire man—the son of Mr. Fred Mercer, the landscape painter—and was born at Abbots Bromley in 1891. His leaning towards the study of agricultural science became apparent at an early age and is confirmed by his career as a student at Harper Adams, the Botanisches Staatsinstitut, Hamburg, and the South-Eastern Agricultural College. He was a graduate in agriculture of the University of London, and held the National Diploma in Agriculture. Before coming to Northern Ireland, Prof. Mercer held appointments as lecturer in charge of the Department of Agricultural Botany at Armstrong College, adviser in agricultural botany for the northern counties of England, and divisional organizer for the Northern Province under the Food Production Department of the Ministry of Agriculture and Fisheries. During 1919–22 he was assistant director and chief research officer in the Seed Testing Station for England and Wales. It was while holding this appointment that he made his survey of seed growing in Great Britain, which is the best known of his earlier work.

On his appointment, in 1922, as head of the Seed Testing and Plant Disease Division of the Ministry of Agriculture for Northern Ireland, he threw himself energetically into the organization of the Northern Ireland Seed Testing Station, where his long experience

and intensive knowledge of seeds and seed testing allowed him to build effectively and have left their mark on this Station as it exists to-day. The study of seeds and allied problems provided his main interest on the research side, and his book, "Farm and Garden Seeds", which is remarkable for the accuracy and beauty of its hundreds of illustrations of seeds drawn in black and white and for the attractive style of its writing, portrays him at his best. His appointment as chairman of the Research Committee of the International Seed Testing Association established his claim to international reputation. His ability was soon recognized by the rye-grass seed-growing industry in Northern Ireland, and his loss will be keenly felt by all those engaged in seed production, who looked to him continually for good advice and wise counsel.

As professor of agricultural botany (1924), dean of the Faculty of Agriculture (1928) and senior technical research officer of the Ministry (1928)—which posts he occupied at the time of his death—S. P. Mercer will be remembered by colleagues and students alike for his width of vision as a teacher, for the conscientiousness of his effort to give sound advice and for his unfailing courtesy. He became dean of the Faculty within a few years of its formation, and during his tenure of this office he succeeded in establishing it on sound lines, and gained and retained the respect of all in so doing. His conspicuous services to agricultural education and research in Northern Ireland were marked by the award of the O.B.E. in 1943.

At the outbreak of war he undertook additional duties in connexion with the control of seed production and distribution in Northern Ireland, and here he was able to bring his knowledge and experience to bear in assuming his not inconsiderable share of "the war effort".

Mercer did not enjoy robust health; he worked under a handicap which few of us are asked to bear, and knowledge of this only serves to emphasize the greatness of his achievements. A lover of peace, prevented by indifferent health from fighting to secure that peace, artist and idealist as well as man of science, gentle and retiring of nature, blessed with constancy of affection, he would have achieved much more had the strength been his and had his span of life been longer. We, his colleagues, mourn the loss of a fine and ardent spirit, an upright and just man rightly disturbed on occasion by the blatant and consistent imperfections existing in our race and grieved at his powerlessness to do more to put wrongs right. A. E. MUSKETT.

## Prof. Leo F. Goodwin

WE record with regret the death of Lieut.-Colonel Leo Frank Goodwin, professor of chemical engineering at Queen's University, Kingston, Canada, on August 15, at the age of sixty-six. He was the elder son of the late Oscar Guttmann, author of "The Manufacture of Explosives" and of "Monumenta Pulveris Pyrii". Prof. Goodwin received his engineering training at the City Guilds Central Technical College and then took his Ph.D. in chemistry at the University of Heidelberg. He was a member of the Institution of Chemical Engineers and of the Engineering Institute of Canada and a fellow of the Institute of Chemistry. He became assistant to Sir William Ramsay at University College and held an assistant professorship for some years at the City College, New York, before taking up his chair at Queen's University. There he inaugurated the first comprehensive course in chemical engineering in the British Empire. An enthusiastic advocate of an undergraduate curriculum for chemical engineers, he probably turned out during the last thirty-five years a larger number of fully qualified and successful chemical engineers than the rest of the British Empire, exclusive of Canada.

His published work dealt mainly with large-scale chemical processes such as the manufacture of pulp for paper, acetone, causticizing and cement colouring, and he was employed as consultant to some of these industries.

Prof. Goodwin also had a distinguished military career, first in the squadron of the Inns of Court Rifles and then in the Princess of Wales Own Rifles, Canada, which he commanded for some years. In September 1914 he came to England with the 1st Canadian Division and served with them in France and Flanders during the critical 1915 campaign. After the battle of Givenchy he was seconded for service with the Canadian Munitions Board and rendered valuable technical service to the British and Allied Governments.

During the present War, Prof. Goodwin again served the Canadian Government in a military and technical capacity, and latterly supervised a number of selected research students engaged on Government sponsored research work. There is little doubt that his early demise was hastened by a long period of overwork.

Prof. Goodwin leaves a widow well known as an artist under the name of Helen Sinclair and a daughter now in the Canadian W.A.A.F. He will be greatly missed by a wide circle of friends here and in America.

R. ROBERTSON.

## Dr. M. C. Mott-Smith

DR. MORTON C. MOTT-SMITH, writer in physics for Science Service, Washington, died on June 9. He was sixty-six years old. Although he joined the staff of Science Service less than three years ago, he had completed since then two important fundamental texts in physics for use in high schools and by soldiers and adult civilians. Of one of these—"Fundamentals of Electricity"—more than 650,000 have been printed, including editions for the use of the American Army and a translation into Spanish.

Dr. Mott-Smith was born in Hawaii on November 26, 1877. He graduated from the Massachusetts Institute of Technology in electrical engineering and obtained his Ph.D. in physics, philosophy and mathematics at the University of Halle, Germany. He was formerly professor of physics at Colby College and George Washington University.

WE regret to announce the following deaths:

Prof. J. C. W. Frazer, research professor of chemistry in Johns Hopkins University, on July 28, aged sixty-eight.

Sir John Jarmay, K.B.E., a director of Brunner, Mond and Co., Ltd., and of other chemical works, on August 22, aged eighty-seven.

Prof. D. E. Smith, emeritus professor of mathematics in Teachers College, Columbia University, on July 29, aged eighty-four.

Mr. H. F. Tomalin, formerly conservator of forests, Ceylon, on August 16, aged eighty-two.

# NEWS and VIEWS

## University of Bristol:

### Chair of Chemistry

It has been announced that Dr. Wilson Baker is to succeed Prof. E. L. Hirst as Alfred Capper Pass professor of chemistry in the University of Bristol. Dr. Baker studied in the University of Manchester and, after a period of service in France with the Friends' War Victims Relief Organisation, he obtained the degree of B.Sc. with first-class honours in chemistry in 1921. He then held successively the Mercer scholarship, the Baeyer fellowship and the Dalton scholarship for research in chemistry, and on taking the Ph.D. in 1924 he was appointed assistant lecturer in Manchester. In 1927 he joined the chemistry staff in the University of Oxford and has also held for some time the position of fellow and prælector in chemistry at the Queen's College. He received the degree of D.Sc. (Manchester) in 1933.

Dr. Baker is distinguished as an organic chemist whose work has developed markedly our knowledge of various groups of natural products. Special reference may be made to his contribution to the chemistry of flavones and *iso*-flavones and the polyhydroxybenzenes. In addition to work on natural products, Dr. Baker has made important contributions to the theory of chelated compounds of the aromatic series, and has given attention to the study of condensation products of phenols with ketones. Along with Mr. T. W. J. Taylor, he undertook a revision of Sidgwick's "Organic Chemistry of Nitrogen", the new edition of which was published in 1937. Dr. Baker hopes to commence his work in Bristol at the beginning of January 1945.

### Chair of Civil Engineering

The appointment of Dr. A. G. Pugsley to the chair of civil engineering at the University of Bristol has been announced. As an acknowledged authority on structures, he will be able to maintain a tradition established by his predecessors, J. F. Baker and A. J. Sutton Pippard. Dr. Pugsley was educated at Rutlish School, Merton, took his London degree in engineering at the Battersea Polytechnic, and followed this by an apprenticeship to civil engineering at the Royal Arsenal, Woolwich, under Colonel H. Mitchell. He then joined the staff of the Royal Airship Works, Cardington, and was engaged upon problems of structural design until the establishment was broken up by the Government's decision to discontinue airship development following the accidental loss of the *R*.101. He transferred to similar work on heavier-than-air craft at the Royal Aircraft Establishment, Farnborough, and later was appointed head of the Structural and Mechanical Engineering Department there. During part of this period he held the appointment, by arrangement with the Air Ministry, of part-time lecturer on aircraft structures in the post-graduate Aeronautics Department of the Imperial College of Science and Technology, South Kensington, London. He resigned this in 1941 owing to pressure of official duties at Farnborough.

Dr. Pugsley's researches have been mainly in the field of elasticity in aircraft structures, upon questions of interaction of aerodynamic loading with structural elasticities and inertias, and the development of airworthiness design regulations putting these into practice. He was awarded the D.Sc. by the University of London for this work. His activities at Farnborough included a notable expansion of the experimental work on structures, including investigation of structural accidents. He was awarded the O.B.E. early in the present year.

## Society for Visiting Scientists

The Society for Visiting Scientists was founded on the initiative of the British Council, and in consultation with the Royal Society, to provide a meeting place and information centre for men of science from overseas visiting Great Britain. The premises at 5 Old Burlington Street, W.1, consist of a lounge and meeting rooms, a bar, refectory, and some dormitory accommodation. These are at the disposal of members. The information centre is open to all visiting men of science, so anyone arriving in Britain can, if he wishes, proceed at once to the House and be given advice and details of how he can apply for membership. Under the present conditions it was decided to postpone the official opening for the time being; but the Society has been functioning unofficially for the last few months and has already been used by a number of British and foreign scientific workers, including members of the French Scientific Mission. It is hoped that an official opening will take place in the near future. In the meantime the Executive Committee has held an informal reception. On this occasion the president, Prof. F. G. Donnan, pointed out the importance of offering hospitality to young scientific workers, and deplored the lack of facilities for them in the past. He added, "I hope sincerely that this modest beginning will be but the nucleus of something much greater and more widely spread, something that in the happy days to come will contribute to the friendship, intercourse, and good fellowship of scientists throughout the world".

## Rehabilitation of Liberated Countries

The rapid advances of the Allies in both eastern and western Europe has brought into prominence the vitally important task of carrying relief to the suffering peoples and helping them to restart their agricultural and industrial activities. Several conferences have recently been held both in Great Britain and in North America dealing with the many important problems involved. The work falls into three stages. During the period of military operations it is in charge of the Civil Affairs Branch of the Army. Military necessities must obviously be of over-riding importance, and the closest liaison with the military authorities is essential. This organization will deal with the emergency period, but ceases to act when the military operations have ceased. At that stage a National Government will take charge, and it can look to the United Nations Relief and Rehabilitation Administration for advice and supplies for completing the relief measures and restarting the agricultural and industrial life of the country.

The work of U.N.R.R.A. falls into several sections: supplies of food, clothing, agricultural materials, machinery and spare parts for restarting damaged factories, especially those concerned with food; and with the returning of the scattered populations to their homes. Expert committees have collected data and worked out bases of allocations and priorities. The combined boards in Washington will furnish the most important supplies, and although reserves of food are not yet available owing to military demands

and those of the Civil Affairs Branch, U.N.R.R.A. has already received substantial allocations of other principal items including clothes, seeds and medical stores. In addition, U.N.R.R.A. has established a claim on crops still to be harvested, on clothes to be made, etc. The agricultural and industrial requirements are closely linked: if, for example, the flour mills could be started, it would be possible to send wheat into the countries assisted; and this would provide not only bread for the people but also milling offals that would produce milk and also animal manure to enrich the soil. Fishing also is to be restarted.

The third stage is reached when the agricultural and industrial life of the country is beginning to function normally; at that stage U.N.R.R.A. ceases to operate as its purposes do not include reconstruction. Organizations have been designed for dealing with the new problems that will arise. A permanent world food and agricultural organization is to be established, and a draft constitution has already been agreed. Its functions will include the collection, analysis and dissemination of information about nutrition, food and agriculture. It will promote and recommend national and international action on research and education in these subjects; also on the conservation of resources, improved methods of production, marketing and distribution, and the provision of adequate agricultural credit; it will also furnish technical assistance to Governments when required. No term is set to the operations of this body.

## A Medical Service in Ethiopia

AN opportunity for immediate medical service—and especially, it would seem, for service by trained nurses—is indicated by an article by Dr. Ruth Young, formerly principal of the Lady Hardinge Medical College for Women, New Delhi, on "Medicine and Nursing in Ethiopia" (*The Lancet*, 797; June 17, 1944). Although it is difficult to assess accurately the incidence of particular diseases in Ethiopia, because no vital statistics exist, Dr. Young has been able to gather valuable information about the physique, diet and general health of the people. The physique of the people living on the plateau is fairly good, and they are strong and hardy. The common diseases are typhus, relapsing fever, pneumonia, venereal diseases, dysenteries, trachoma and such parasitic diseases as scabies, tropical ulcer, infestations with intestinal worms and malaria. Leprosy is fairly widespread; but tuberculosis is apparently not so serious a problem as it is in other parts of Africa, nor do diseases due to deficiencies in diet seem to be common. From what Dr. Young says there would seem to be as much need of agricultural and veterinary assistance as of medical help. The cows are poor milkers and, although goats are numerous, they are kept chiefly for meat and skins and are not much milked. On the other hand, any increase in production of animal food products would, it seems, be largely neutralized by the numerous fasts imposed by the Coptic Church, which, apart from a longer Lent than ours and other fasts, forbids the use of foods of animal origin on two days of every week. Butter, milk and eggs are included in these forbidden foods.

Maternal mortality is apparently low, and complications at childbirth are not common. Dr. Young attributes this to the fact that most births are normal and to the very strong prejudice against any kind of interference at childbirth. There is no class of professional midwives similar to that which does "such untold damage in a country like India". Infant mortality is, on the other hand, probably very high. From questions addressed to women, Dr. Young learned that 176 out of 353 children born alive had died, and she concluded from the evidence available that something like 109 of these had died before the age of one year. There is also a high rate of sterility, probably due mainly to syphilis which, like gonorrhœa, is common. The chief needs at the moment are, Dr. Young thinks, intensive preventive work and the teaching of mothercraft and hygiene rather than the provision of hospital beds. There are at present no properly trained nurses. In an annotation on this interesting article, *The Lancet* (795; June 17, 1944) refers to the hospital to be built in Addis Ababa in memory of the late Princess Tsahai. Most of us will remember the tragic death of this young daughter of the Emperor at the age of twenty-two. In Great Britain, while she was in exile, she qualified as a State registered nurse after training at the Great Ormond Street Hospital for Sick Children, London, and later she took further training at Guy's Hospital. Returning home, she married the governor of a province in Ethiopia and began to organize the health service which she wished to see in her own country.

## Simple Teaching Apparatus in Physics

IN his presidential address given to the Essex Science Teachers' Association, Lord Rayleigh asks, and discusses, the question "Are Expensive Appliances Necessary?" In the physical laboratory a great deal can be learnt about Wheatstone's bridge by means of a wire stretched along a rough board, graduated with ink or pencil marks, with a piece of metal held in the hand to make contact with it at any point. From a purely teaching point of view this is as good, if not better than, a post-office box costing as many pounds as the other does pence. It is much less likely to muddle the beginner and will in all probability give him more insight into the physics of what he is doing. If the student has rigged it up for himself he will further get a sense of independence and achievement which he never gets by handling the elaborate constructions of the instrument maker. It is not uncommon to find people who regard an optical instrument not as an arrangement of reflecting and refracting surfaces, but as a construction of lacquered brass. The schoolboy first regards a telescope as a thing which 'pulls out'. All the essentials of the instrument can be better appreciated by sticking lenses with 'Plasticene' on a strip of wood. Helmholtz told Lord Rayleigh that as a boy he made his own telescope out of spectacle lenses and a cardboard tube. In instruments made by the instrument maker many essential parts are rightly hidden from view by protective devices, and the young student is deterred from meddling with them for fear of damaging valuable property.

## Simple Apparatus in Physics Research

IN the same address Lord Rayleigh claims that beginners in research also should be "graduates in the school of string and sealing wax". Faraday, and Maxwell in such constructions in the Cavendish Laboratory as his model of the thermodynamic surface, are each quoted as examples. Sir Charles Parsons, the greatest mechanical engineer of his generation, was able to deal with formidable problems

of large-scale construction, yet he found paper, sealing wax, wire and steel knitting needles very adequate materials for making a working model of his air turbine. When the late Lord Rayleigh had occasion to set up a pair of mirrors for Fresnel's interference experiment he mounted them in a few minutes on two lumps of soft wax. The amateur method is not only much cheaper but also often takes little more time than the dispatch of an order to the instrument maker. Progress, too, can be made while the mind is red-hot upon the project, before delay has cooled enthusiasm. Little sympathy is shown for the research worker who puts the responsibility for designing his apparatus upon a firm of instrument makers. Lord Rutherford is quoted as saying that, if necessary, he could carry out research at the North Pole. J. C. McConnel, who was compelled for health reasons to winter in Switzerland out of reach of laboratories or facilities of any kind, still made important observations on the crystallization of ice, noting in particular how large were the individual crystals and how they behaved under bending forces when single crystal rods were cut in various directions. Lord Rayleigh paid a tribute to the instrument making industry and its part in practical life and non-pioneering research.

## The New Carnegie Cyclotron

A NEW giant cyclotron has recently been put into operation at the Department of Terrestrial Magnetism of the Carnegie Institution of Washington. The new cyclotron, one of the two largest in operation in the world (the other being at Berkeley, California), generates particles of 15,000,000 electron volts energy, permitting the most precise measurements ever made of the forces released by atomic disintegration. The cyclotron itself weighs more than 225 tons, has an overall height of 12 ft.; it is 30 ft. long and 20 ft. wide. It took four years to build, at a total cost of 500,000 dollars for the cyclotron, its appurtenances, and the special three-story building housing the equipment and instrument shop. The magnet is made up of four iron castings, the largest weighing more than fifty tons. Surrounded by this heavy magnet is the accelerating chamber, about sixty inches in diameter, in which atomic particles are produced. The cyclotron is housed ten feet below ground.

## A New Type of Still

THE *Bulletin and Laboratory Notes* of September 1943, issued by Messrs. Baird and Tatlock, Ltd., Esher, Surrey, contains a description of an interesting copper and glass still for the preparation of distilled water in the laboratory. The water is boiled by an electric immersion heater in a tinned copper boiler, with a water-sealed lid of the same material. The lid carries a central metal tube over which is a glass hood communicating by a backward-sloping glass tube to the special water-cooled spiral glass condenser. A horizontal baffle inside the lid under the central steam outlet minimizes the passage of spray into the hood, which also serves as a trap. More than 90 per cent heating efficiency is claimed. The standard model has a 1·8 kW. motor and produces 2·7 lit. of distilled water per hour, with a total water consumption of 36 lit. The water, in a particular experiment, had a *p*H of 6·0–6·2, and conductivity 1·5–2·0 gemmohs, although these figures will vary with the quality of the tap water. Oil or gas heating may be used in emergency. The whole apparatus is conveniently mounted in one piece by suitable clamps and appears to be very robust, and an additional feature is that a supply of hot cooling water can be diverted to a tank near a sink and used for washing. Other interesting types of stills are also described in the *Bulletin*.

## Institute of Industrial Administration: Awards

THE Institute of Industrial Administration has awarded the Institute travelling scholarship to Mr. A. G. Irvine for his thesis on "The Purposes and Techniques of Market Research". This scholarship, of the value of £250, enables the holder to spend three months in the United States studying American practice in his particular field of management, assisted by the New York office of the donors of the scholarship, Messrs. Stevenson, Jordan and Harrison, Ltd. The Wilson Medal of the Institute has been awarded to Mr. A. W. Goldstaub, for his paper on "Internal Audit in Industry". The Junior Executive Prize of books to the value of £5 has been won by Dr. W. L. Kent, for his paper on "The Application of Science to Industry", and Mr. G. Kinnaird Evens, for his paper on "The Future of Psychology in Industry".

## "Books: The Warehouse of Knowledge"

WITH reference to the leading article "Books: the Warehouse of Knowledge", published in *Nature* of September 9, p. 319, Mr. Stanley Unwin writes: "If the established book publishers had as much as 5 per cent of 'the paper in the country available for printing' they would be in clover. The total of 420,000 which you give merely includes four categories of paper consumers and omits all others such as the printers. At the beginning of the War it was estimated that books called for about 1½ per cent of the total. It is unlikely even to-day that the figure exceeds 2 per cent." We regret our error in stated percentage of paper available, and since it was a considerable over-estimate, Mr. Unwin's correction adds still further point to our argument. It may be possible, however, that even Mr. Unwin's figures need correction, so far as books are concerned, for, as *The Bookseller* of September 14 points out: "These usages, however, do not consume all the paper available for printing. There is, in addition, an unknown but obviously considerable quantity of printing paper employed outside the above categories; for instance, the paper used in company reports, trade catalogues, and for a large variety of other commercial purposes".

## Announcements

THE title of reader in timber technology in the University of London has been conferred on Dr. F. Y. Henderson in respect of the post held by him at the Imperial College of Science and Technology.

MR. F. E. HUGHES (assistant conservator of forests, Gold Coast) has been appointed senior assistant conservator of forests, Gold Coast.

ACCORDING to the August issue of the *Anglo-Swedish Review*, the birth-rate figure in Sweden for the first quarter of 1944 of 33,261 was the highest recorded for this period since 1921; the figures for the corresponding period in 1943 and 1942 were 30,079 and 26,240 respectively. More children were born in the towns than in the country, the birth-rate figure for Stockholm being especially high.

# LETTERS TO THE EDITORS

## Phytic Acid and Phytase in Cereals

The interesting letter of Dr. R. A. McCance and Miss E. M. Widdowson in *Nature* of May 27[1], in which they point out the relatively large quantity of phytase in wheat as compared with oats, gives me the opportunity of recording some further facts on this important practical issue which supplement those given in the letter. This is no mere academic question, but concerns what in the past certainly has been, and in my view possibly still is, the most prominent problem of malnutrition affecting people in Great Britain.

Cereals form such a large part of the national dietary, namely, about 50 per cent, that, if they have a nutritional defect, it is certain to be of great consequence to health and development. What we must aim at is to get all the advantages of these valuable foods and at the same time to eliminate or prevent any baneful action they may have. Now, cereals have such a defect in that they are not only poor in calcium content but also they can, under some conditions, interfere with the availability to the body of calcium of other foods[2]. This is of special importance to the child and adolescent, whose needs for calcium to incorporate in the growing bones, the developing teeth and other organs are great. In the adult animal also cereals can denude the bones of their calcium salts under some conditions. Contrary to all expectation, cereals such as oatmeal and maize, which contain most calcium, are just those which can interfere most with calcium deposition during growth.

In 1939 it was found that one substance in cereals which plays a large part in this harmful action is phytic acid[3]. Any form of treatment which reduces the phytic acid in cereals either by eliminating it or by hydrolysing it will reduce the rickets-producing or anticalcifying effect. It was found that malting of cereals, and, more especially, germination followed by autolysis of the crushed grain, reduce this action; and now McCance and Widdowson have emphasized the importance of the hydrolysis of phytic acid that accompanies the change from flour to bread as the result of the action of the abundant phytase in the flour. They point out that oats and oatmeal, on the other hand, contain but little phytase to break down the phytic acid. They suggest that the difference in phytase content of wheat and oats explains the results described many years ago of the smaller rachitogenic action of bread as compared with oatmeal[2].

That this explanation is true is undoubted, but it is only part of the truth. Oats and wheat are both rich in phytic acid. In my experience oats are the richer source, but the variation in different samples of both grains is large and for the purpose of the argument we will assume that the amount is the same in each cereal and of the order of 200 mgm. phytic acid phosphorus in 100 gm. of the grain. Now the husk which is removed in the preparation of the oatmeal forms about 30 per cent by weight of the grain, and since this husk contains no phytic acid (it does contain a little phytase) the percentage of phytic acid in the dehusked grain rises correspondingly, namely, up to 270 mgm. or more of phytic acid phosphorus per 100 gm. oatmeal. On the other hand, in processing wheat to flour, assuming that the wheat-meal flour is of 85 per cent extraction, the 15 per cent removed in the milling is largely made up of the coarser bran, which is very rich both in phytic acid and phytase. Thus 85 per cent extraction wheat-meal flour would contain about 120 mgm. or even less phytic acid phosphorus per 100 gm. flour. Starting, therefore, with oats and wheat grain both containing 200 mgm. phytic acid phosphorus per 100 gm. of grain, by the time each preparation reaches the cook, there is a great difference between their contents: 270–300 mgm. phytic acid phosphorus in oatmeal and 120 mgm. in national wheatmeal flour; and this is not the end of the story.

In preparing these products for the consumer, the cook again alters their relative phytic acid content. The oatmeal is boiled as porridge, its small phytase content is destroyed and the phytic acid remains at the same high figure. In the case of wheaten flour, the matter is different. The high phytase content gets a chance of destroying phytic acid in the flour during the period when the dough is standing. In this process, however, the flour phytase is not the only phytase present. The added yeast is also rich in this enzyme, and it may, under some conditions, assist the hydrolytic breakdown of phytic acid. Whether it does so assist seems to depend on the method of bread-making adopted. If the amount of yeast added is relatively large (2·1 per cent of flour) and the time of standing of the dough short (2 hours), the yeast may add largely to the phytic acid destruction. If, however, the yeast added is small (0·6 per cent of flour) and the dough rising-time long (6 hours), the yeast phytase may be ineffective. The phytase action of both flour and yeast is greatly increased as the $p$H is lowered towards 4·5, and it is possible that the additive effect of the larger amount of yeast may be partially or wholly explained by this change in $p$H. The accompanying results obtained on baking bread with flour at two levels of phytic acid content illustrate this effect of yeast.

HYDROLYSIS OF PHYTIC ACID IN BREAD-MAKING

| | Mgm. phytic acid phosphorus | | | |
|---|---|---|---|---|
| | Wheat-meal flour per 100 gm. | In bread per 100 gm. flour | Hydrolysed by phytase in 100 gm. flour | Probably hydrolysed by yeast per 100 gm. flour |
| SPECIMEN 1 | | | | |
| (a) High yeast; short rising time: | | | | |
| (x) living yeast | 75 | 29 | 25 | 21 |
| (y) dead yeast | 75 | 50 | 25 | 0 |
| (b) Low yeast; long rising time: | | | | |
| (x) living yeast | 75 | 26 | 46 | 3 |
| (y) dead yeast | 75 | 29 | 46 | 0 |
| SPECIMEN 2 | | | | |
| (a) High yeast; short rising time: | | | | |
| (x) living yeast | 174 | 77 | 76 | 21 |
| (y) dead yeast | 174 | 98 | 76 | 0 |
| (b) Low yeast; long rising time: | | | | |
| (x) living yeast | 174 | 60 | 114 | 0 |
| (y) dead yeast | 174 | 57 | 117 | 0 |

High and low yeast = 2·1 per cent and 0·6 per cent respectively.
Short and long rising time = 2 hours and 6 hours respectively.

Finally, it may be asked, what are the nutritional implications of this phytic acid–phytase problem of cereals? In the normal high cereal diet, three situations are presented: (1) when it contains much phytic acid, as when oatmeal or maize meal is largely eaten; (2) when it contains much inositol and phosphoric acid produced by hydrolysis of phytic acid by phytase, together with some unhydrolysed phytic acid, for example, when bread made from high extraction flour is eaten; (3) when it contains but little phytic acid or hydrolysed phytic acid, as when bread from low extraction flour or when a cereal such as rice is eaten. Since both inositol and phosphate are essential constituents of the diet, it is clearly desirable to have good supplies of these in the food, that is, conditions (1) and (2) above, but only so long as (*a*) these substances are available to the body and (*b*) neither phytic acid nor its product phosphoric acid is allowed to exert its calcium-stealing influence. Both these necessary conditions can be obtained by increasing the calcium in the diet and by maintaining a sufficiently high vitamin D intake. Man, especially the Scot, instinctively found the answer to this problem in the case of oatmeal by taking milk freely with his porridge. That is also the *raison d'être* for the present practice of adding calcium carbonate to the modern loaf and vitamin D to the margarine, although it is probable that, in both cases, the present supplements are too small for the optimum calcium-phosphorus nutrition of many people.

## Catelectrotonic Potentials in the Dorsal Roots of the Spinal Cord

THE preparation has been the isolated oxygenated spinal cord of the frog. It is well known[1,2] that a dorsal root volley gives rise to a prolonged negative potential which is propagated electrotonically from the spinal cord along that root and also along other dorsal roots both ipselateral and contralateral. In adjacent ipselateral roots this dorsal root potential may be as large (10 mV.) as in the root of entry.

With submaximal volleys the dorsal root potential rises to a rounded summit in about 20 msec. and then decays approximately exponentially with successive half-times of about 30–60 msec. With larger volleys there is usually a prolonged negative 'tail' which is attributable to long-continued activity of the internuncial neurones of the spinal cord, and is paralleled by prolonged after-discharge from the motoneurones. In conformity with this explanation, the tail is increased in size and duration by rapid repetitive stimulation and after soaking the cord in strychnine (1 in 200,000).

An antidromic volley in the ventral root fibres also sets up in adjacent dorsal roots a prolonged negative potential which has a longer latent period and a slower rise to a more flattened summit, but which decays at least as rapidly as the dorsal root potential set up by a dorsal root volley (half-times 25–45 msec.). This decay is always exponential, and never shows any prolonged tail.

If the spinal cord is anæsthetized by soaking in nembutal solutions, the rising phases of both types of dorsal root potential are not appreciably altered, but the decaying phases of both are greatly prolonged. Moreover, the abolition of activity in the internuncial neurones is associated with a removal of the tail of the dorsal root potential set up by dorsal root volleys (single or repetitive), which consequently now decays in a strictly exponential fashion, closely resembling the decay of the dorsal root potential set up by the ventral root volleys. The 'half-times' are lengthened 10–20 times by 1 in 7,000 nembutal, ranging with this latter dose between 0·4 and 0·7 sec. Further increase in dosage abolishes the dorsal root potential set up by ventral root volleys.

The exponential time course of the decay suggests that, as with the synaptic potential produced in the motoneurones[3], the dorsal root potential is produced by the relatively brief action of an actively depolarizing agent, the decaying phase of the dorsal root potential being relatively passive (except for the internuncial activity) and governed by the electric time constant of the membrane being depolarized. This analysis of the dorsal root potential into active and passive phases is supported by the effect of nembutal, which (apart from the removal of any internuncial activity) can be simply explained as due to a lengthening of the time constant of the membrane. This time constant is a product of impedance and capacity, and since the capacity of living membranes is but little altered even during extreme changes in the time constant[4], it seems likely that nembutal produces a large (10–20-fold) increase in the electric impedance of the membrane. It has long been suspected that anæsthetics act in this way[5,6]. However, in the spinal cord this effect appears to be largely restricted to certain membranes; for the electric time constant of the motoneurones remains short even under deep nembutal anæsthesia, the half-time for the synaptic potential being about 25 msec. in the frog[3].

The location of the membranes responsible for the dorsal root potential has been investigated by setting up a maximum volley in a dorsal root at all phases of a dorsal root potential produced in that root by a previous volley in that or another dorsal root, or a ventral root. There is an immediate destruction of a large fraction of the dorsal root potential in that root (usually 50–90 per cent, but with some roots as small as 20 per cent), but no effect on the dorsal root potentials in other roots.

On the basis of these experiments, it is suggested that the dorsal root potential is a catelectrotonic potential set up in the central terminals of the dorsal root fibres by the actively depolarizing action of potentials produced in nerve cells in close proximity, particularly in synaptic contact. With the dorsal root potentials set up by dorsal root volleys, the time course of the actively depolarizing action (determined by analysis) is such that it could be produced by the synaptic potentials set up in those nerve cells by the dorsal root volley. This suggestion would explain the extensive distribution up and down the cord of the dorsal root potential produced by a volley in one dorsal root. The decay of the dorsal

root potential would be governed by the time constant of the membrane of the terminal nerve fibres of that dorsal root, and it would be these terminals that are specifically affected by nembutal. The partial destruction of the dorsal root potential by a maximum volley in that root suggests that the impulses do not penetrate to all the central terminal nerve fibres of that root. This suggestion recalls the findings of Renshaw[6] and Lloyd[7] that an antidromic impulse in a ventral root fibre may fail to spread over the surface of the motoneurone of that fibre, block apparently occurring at the axon hillock.

## Mechanism of Burrowing in *Arenicola marina* L.

If a living lugworm is put on the surface of wet sand or mud, it curves its head downwards and burrows in. During the burrowing act (which was described in detail by Just[1]), the proboscis is extruded and withdrawn, wave-movements of a characteristic kind travel forwards along the body, and the notopodia are directed backwards.

According to many authorities, the lugworm swallows sand as it burrows. Thus Stannius[2] wrote: "Legt man eine ausgegrabene Arenicola auf eine von Seewasser etwas bedeckte sandige Stelle des Ufers, so fängt sie alsbald an, eine Röhre im Sande sich zu bohren. . . . Die Röhren entstehen aber nicht ausschliesslich dadurch, dass die Würmer den Sand oder den Schlamm an die Seite drücken, sie verschlingen vielmehr beim Bohren beständig Sand; der ganze Darmkanal wird davon angefüllt, und ehe der hinterste Theil des Thieres die Oberfläche des Bodens ganz verlässt, wird der verschluckte Sand durch den After wieder entleert." Ashworth[3] concludes a description of burrowing with the words "By these means, a passage is eaten and forced through the mud".

When those passages were written, the mode of life of the lugworm was not well understood. In particular, burrowing and feeding were supposed to be one and the same process. More recent work, however, indicates that the two are quite distinct[4]. The worm is now believed to excavate an *L*-shaped gallery, and to lie with its head at the blind end, eating the surrounding mud. I therefore made the following experiments, to find out whether significant amounts of sand or mud are in fact swallowed during burrowing.

(1) *Weighing experiments.* Lugworms were first weighed, then allowed to burrow until only the tip of the tail could still be seen, then dug out and weighed again. The anus was watched, and, if the worm defæcated during burrowing, that particular experiment was discarded. Usually, however, defæcation did not occur. Of the successful experiments, two were done on the beach at Bangor, the worms being allowed to burrow as soon as they were dug up, and the rest in the Department of Zoology of the University of North Wales, using muddy sand from the beach. Generally there was a very slight loss of weight during burrowing (see table). The density of the wet, muddy sand was about 1·9, so it seems that significant amounts cannot have been swallowed.

| Situation | Worm No. | Weights (gm.) Before burrowing | After burrowing | Difference |
|---|---|---|---|---|
| Beach | 1 | 4·0 | 3·8 | —0·2 |
| | 2 | 7·5 | 7·3 | —0·2 |
| Laboratory | 3 | 3·8 | 3·8 | 0·0 |
| | 4 | 7·0 | 6·9 | —0·1 |
| | 5 | 8·2 | 8·1 | —0·1 |
| | 6 | 12·3 | 12·3 | 0·0 |

(2) *Dissection experiments.* Five worms were kept in clean sea water in the laboratory for from three to four weeks. Three of them were then allowed to burrow into sand from the beach, as described above, then dissected under 8 per cent magnesium chloride, which acts as a narcotic[5]. The other two were dissected without preliminary burrowing. In the two controls, there was no trace of sand in any part of the gut. In the worms which had burrowed, small amounts of sand were found in the œsophagus, but there was none in any other part of the gut. One of the three had a single, minute mass of sand, comprising only some half-dozen sand-grains; the second had a single, compact mass, 2–3 c.mm. in volume; and the third had most of its œsophagus incompletely filled with a cylinder of sand. In all cases, the amounts ingested were negligibly small, compared with the volume of a whole worm.

Clearly, the idea that Arenicola passes through the sand like an animated cork borer is fallacious. Burrowing is achieved by thrusting the sand, or mud, aside; very little, if any, is taken in through the mouth. The proboscis is used in burrowing, and also, presumably, in feeding[6], so it appears to be capable of widely different types of action.

In conclusion, a note may be added about the remark of Stannius[2], quoted above, that defæcation accompanies burrowing. I saw defæcation during burrowing in two of four worms on the beach, and never in the laboratory. The worms used in the laboratory had been kept in clean water for a couple of days at least, and had partly or completely emptied their intestines. I think it likely that the defæcation occurs only in replete worms, as a pressure effect of some kind incidental to burrowing. Perhaps those which defæcated would shortly have done so in any case, even if they had not been disturbed.

## Sewage Bacteria Bed Fauna in its Natural Setting

It has been observed that the bacteria beds of sewage works form an environment for insects unlike anything in Nature[1]. The depth of the habitable zone is great, so that compared with most insect habitats it is almost like the cube against the square. It is well aerated and constantly supplied with a basic food supply both in solution and in finely divided form evenly spread over the bed. The temperature is protected from extremes, on one hand by the heat generated by vital processes and on the other hand by the effects of evaporation. The daily temperature swing is restricted. Larvæ and pupæ are not accessible to birds except at the surface. This insect fauna is characterized by the small number of successful species and the great prevalence of those few which do succeed. In eight years of trapping on the Knostrop beds at Leeds, more than half a million insects were caught and scrutinized; and, though in all about a hundred species were taken, 99·7 per cent of the total belonged to six species of nematocerous flies, namely, *Metriocnemus longitarsus*, *M. hirticollis*, *Spaniotoma minima*, *S. perennis*, *Psychoda alternata* and *P. severini*. The enchytraeid worm, *Lumbricillus lineatus*, has an abundance equal to, or perhaps surpassing, that of any of these larvæ in the Knostrop beds. At some works, though not at Leeds, *Psychoda cinerea* and *Anisopus cinctus* show a similar prevalence. The collembolan *Achorutes viaticus* and the cordylurid fly *Spathiophora hydromyzina* are the only other insects so far recorded as prevalent in the beds.

I have recently located this fauna almost intact, though mingled with a number of other successful forms, in the natural setting of a mud flat about four miles from the nearest sewage works. A small, slightly contaminated stream passes under a bridge and, as an effect of an eddy, forms a mud flat about thirty yards long and fifteen yards wide with a surface usually an inch or two above water level. It is constantly water-logged through seepage, but is rarely flooded and then only for brief periods after heavy rainstorms, for there is a sill a short distance downstream giving a rapid recovery to normal level. It is overhung by trees and receives in autumn a thick carpet of leaves which is absorbed into the mud in winter and largely disintegrated by summer. Samples of the surface mud taken to the laboratory have yielded 1,500 insects, of which 44 per cent belong to eight of the ten species enumerated above as forming the insect fauna of the bacteria beds, Achorutes and Spathiophora only having not appeared in the cultures. Of the others emerging, 31 per cent is shared equally between the blood-sucking genus Culicoides and the short-palped crane-flies, Limoniinæ, both of which have very rarely appeared in collections from the bacteria beds. The characteristic enchytraeid worm of the sewage bed, *L. lineatus*, also occurs in the mud flat, but in numbers is almost masked by a swarming tubificid worm densely clustered just below the surface.

Thus it appears that the macrofauna of the bacteria bed is derived from that of the organic mud flat, but the two types of environment are not much alike. The mud flat, however, does rather resemble the sand sewage filter. In this a bed of porous sand some four feet deep is flooded at frequent intervals with settled sewage which seeps through and is purified in passage. A mat of cellulose and other débris forms on the surface, and when this has thickened and dried it can be rolled off like a carpet, leaving the filter again porous and receptive to further dosing.

This discovery of the bacteria bed fauna in its natural setting should help in the study of its theoretical aspects which hold much of interest, especially in regard to animal competition[2,3,4]. It is also of practical interest since the invasion of dwellings by sewage flies is often a matter of concern to sanitary authorities and it is important to know from what other sources they may come.

## Imperial Forestry Institute, Oxford

In commenting in *Nature* of July 15, p. 94 on the 1942–43 report of the Imperial Forestry Institute, it is stated that there is difficulty in distinguishing between the respective parts played by the Imperial Forestry Institute and the University Department or School of Forestry. This is simply explained by the fact, set out at length in the 1937–38 report, that in 1938 they became a single organization supported jointly by the Colonies, the Forestry Commission, the University of Oxford and a few smaller contributors. At the same time, the information branch of the Institute was taken over by the Imperial Agricultural Bureaux to constitute a new Imperial Forestry Bureau which still works in close collaboration with the Institute. This latter change resulted in a transfer to the Bureaux of nearly all the original Dominion support for the Institute, leaving the Colonial Empire in a still more predominant position among the supporters of the Institute.

The amalgamation of School and Institute was made primarily for administrative reasons and to fit in with the new arrangements for the training of officers for the Colonial Forest Service; it did not affect the research work being done by the staff. This latter work continues to be directed towards Empire needs and interests so far as is possible in Great Britain. In several fields, however, for example sylviculture, there is not a great deal having a direct bearing on Empire forestry that can be done in Britain. Research in these subjects is accordingly directed more towards fundamental problems and problems representative of types likely to occur anywhere, and it has to be carried out in the woods and forests accessible from Oxford. Such studies are clearly likely to be more productive and useful if undertaken in co-operation with the related research activities of the Forestry Commission.

From the educational point of view, it is essential, for keeping the teaching live and practical, that the staff should be in the closest possible touch with current practice and developments where the teaching is done. Moreover, the Forestry Commission looks to Oxford, as having the only University Forestry School in England, to play its part and undertake its share in forestry education for service at home as well as abroad, and in forestry research of a fundamental nature. It was for these reasons that

it was felt desirable to await the publication of the Forestry Commission's plans before deciding on some aspects of the future teaching and research organization at the Institute. If the stress in the report appears to be on the importance of closer co-operation in research with the Forestry Commission, this was only because there appeared to be room for it, whereas decisions affecting Colonial forestry had already been agreed. The expected White Paper has since been published; it was considered by the University Committee for Forestry, which found that no further changes in its own plans were necessitated.

This opportunity may be taken to add that forestry has recently been made an Honour School in this University, as from the next academic year; two years study of biological and physical science will normally be required before the two years forestry courses are undertaken, as was already the position under the statute of 1938.

## Structure of Cellulose

IN their criticism of my suggested structure of cellulose[1], Astbury and Davies[2] appealed to evidence not then available to me in a thesis by Dr. C. J. Brown[3]. My thanks are due to Dr. Astbury for bringing this interesting work to notice and to Dr. Brown for the opportunity to read it. I do not think that it settles the issue between the angles 110° and 90° at the oxygen of the pyranose ring. The difference amounts to $\pm 0 \cdot 15$ A. in the *b* co-ordinate of C1 and C5 respectively, whereas the author, rather modestly, claims only an accuracy of $\pm 0 \cdot 4$ A. The features referred to by Astbury and Davies describe a regular six-sided figure—I presume they would not suggest that this is a precise description.

In "the most detailed saccharide crystal analysis so far reported", Cox and Jeffery[4] conclude in favour of a slightly flattened form of the Sachse *trans* form. This is the form I adopt and, moreover, the strainless arm-chair form, though Dr. Astbury does not appear to recognize it nor appreciate its comfort. In these, as in other studies, reasonable agreement is found with forms based on the 110° assumption, but it remains to be proved that the error in a trial of 90° must be significantly greater.

Meyer and Misch[5] also assume 110°, but I cannot reproduce their parameters from their geometrical assumptions. A unit of length to fit into the 10·3 A. identity period can be obtained by assuming a regular ring of bonds of length 1·50 A. (mean of 4 C–C and 2 C–O bonds) but this is too crude an approximation. My calculations of the rigorous form, with the screw axis as shown by Meyer and Misch, give a length of 11·12 A. (Curiously enough this is longer than it would be if the ring were a regular figure of 1·54 A. bonds.) With another choice of axis, the chain might be buckled into the cell, but I have been unable to find a probable form in conformity with the geometry and with the clearest features of the X-ray diffraction, from the ($h$ 0 $l$) zone.

Cox[6] recognizes that the form of the molecule may be modified by intermolecular forces. This consideration should modify any dogmatism about the unknown form of the cellulose ring, but it does not seriously affect the power of his elegant argument for a nearly co-planar arrangement of the sugar ring carbons[7].

It must be admitted that direct evidence to decide between 90° and 110° for the oxygen angle in the cellulose ring is lacking. If Astbury and Davies, Cox and Brown, Meyer and Misch, Haworth and others assume an unstrained angle of 110°, they may do so in good company—but Pauling[8] as well as Peirce must be excluded from the company.

The variation of the oxygen angle shows it to be deformable. If one sees an elastic thread under an evident load, it is no speculation to assume that its unstrained length is less than the observed length. In $H_2O$, the oxygen angle is 105° and it is distended by the ionic character of the H fields. This ionic character is less in $F_2O$ and the angle is less, 100°. In $H_2S$, the greater separation of the H fields means less repulsive stress and the angle is 92°. (These are the values quoted by Pauling[8].) When large groups are attached to the two bonds, the angle is correspondingly large, attaining 130° and more in the diphenyl ethers[9,10]. All this is in perfect accord with Pauling's theory, that the oxygen bonds arise from *p* electrons and are unstrained at 90°.

It is true that atoms of the appropriate size to enforce an angle of some 110°, Cl (in $Cl_2O$) and C, are not infrequently involved, but this obviously strained angle of a soft atom is not to be confused with the tetrahedral angle of the hard and symmetrical carbon atom. The latest figures on the aliphatic ethers give values of 110° or less[11], and these are clearly strained by an otherwise unbalanced repulsion between the closely held carbon atoms. Dioxane (110°)[12] looks more like a pyranose ring but, by symmetry, the field round each oxygen atom must be closely similar to that in dimethyl ether. When the two carbon neighbours of the oxygen are held also by a line of three carbon atoms, these can take some of the stress from the oxygen bonds and even impose an opposite strain, if there be a minimum of free energy when a line of carbon atoms is co-planar.

The position seems to be, therefore, that the unstrained angle is 90° and the strain is unknown—so the simplest assumption is the strainless form, as given in my note. The fact that it fits so neatly into the cellulose lattice commends it, but I would be the last to claim for the resultant structure any status beyond that of a tentative, approximate speculation, possibly useful as a working hypothesis to correlate the general body of data: and this is all that I would allow to any detailed crystal structure ascribed to a macromolecular fibre.

The parameters are given to 0·01 A. because they express the geometrical consequences of assumptions reasonably defined to that degree of accuracy. This basic, strainless form may later be strained to accord with direct evidence still to be found, but it seems worthy of inclusion in 'trial and error' studies. To that end, it was offered through the speedy channel of the correspondence to *Nature*.

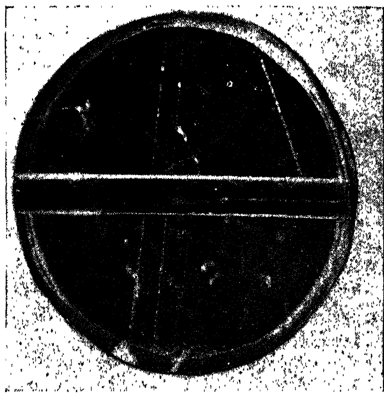
## Cloud Chamber Photographs of Penetrating Showers

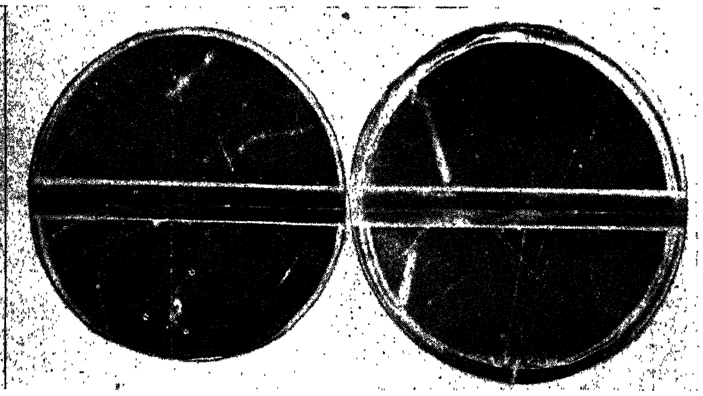
In a long series of counter experiments, Wataghin, de Souze and Pompia[1], and Jánossy[2] and his co-workers have established the existence of showers of penetrating particles different from electron cascade showers and knock-on showers. It now seems probable that the theory of cosmic-ray mesons put forward recently by Hamilton, Heitler and Peng[3] can account satisfactorily for these showers in terms of mesons (and neutrettos). These particles are assumed to be created by protons (or neutrons), of energies greater than $2 \times 10^9$ eV. by cascade or multiple processes.

More direct confirmation of this interpretation of the experimental results is desirable, and for this reason we have recently set up a cloud chamber controlled by a set of counters which selects penetrating showers. The counter sets are arranged in three trays and are connected in sevenfold coincidence such that 95 per cent of all coincidences are caused by penetrating showers. The middle and bottom trays are surrounded by lead 15 cm. in thickness, and the total vertical thickness of lead is 53 cm. Electron cascade showers are thus effectively cut out. The top tray is covered with lead 5 cm. in thickness, and the cloud chamber is placed between the middle and bottom trays.



1

Fig. 1. An example of a shower of penetrating particles produced by a multiple process. Three particles can be seen passing through the lead plate.



2*a* 2*b*

Fig. 2. Two examples of showers of penetrating particles produced by a cascade. In (*a*), two particles can be seen to pass through the lead plate, whereas in (*b*) three (and possibly four) particles pass through the plate.

Some thirty photographs have been obtained so far, and of these, eighteen photographs show penetrating particles which pass through a lead block, 2·3 cm. in thickness, without multiplication. Nine of the eighteen photographs show showers consisting of two or more penetrating particles.

The results are consistent with the assumption that almost all penetrating showers contain ionizing penetrating particles. Further, they show that the ionizing particles themselves are penetrating, and are not soft ionizing secondaries to a non-ionizing penetrating radiation. The ionizing penetrating particles may, however, be accompanied by non-ionizing particles (for example, neutrettos).

Showers of two main types occur among the nine photographs. The first type, typical of almost all the published photographs of showers of penetrating particles, consists of penetrating particles originating at one point, that is, particles produced by a multiple process. Jánossy[2] has shown that these showers are to be expected from the theory of Hamilton, Heitler and Peng if the incident proton (or neutron) has an energy between $2 \times 10^9$ eV. and $2 \times 10^{10}$ eV. An example of this type of shower is reproduced in Fig. 1.

The second type of shower, two examples of which are reproduced in Fig. 2, consists of penetrating particles coming from different directions. It seems probable that this type of shower is an example of the production of penetrating particles by a cascade process[3,4].

Bose, Choudhuri and Sinha[5] have recently published a photograph which they claim shows the production of mesons by a cascade process. To establish such a claim it is first necessary to prove that the shower is not an electron cascade, for electron cascade showers are very frequent while penetrating showers are rare; and it is insufficient to state that the shower contains mesons. Moreover, the one group of particles on Sinha's photograph which clearly passes through the lead plate in the cloud chamber emerges accompanied by several electrons. It is assumed that these are knock-on electrons produced by mesons, but this is very unlikely as the chance of a number of mesons producing several knock-on electrons is negligibly small. The multiplication of the particles in passing through the lead plate is, in fact, a clear indication that they are electrons and not mesons.

## Volcanic Contributions to the Atmosphere and Ocean

If it be assumed, as is now again the fashion, that the nascent earth passed through a liquid stage, it is obvious that "the molten spheroid . . . retained, occluded within itself, some large part of the water in the present hydrosphere, as well as much of the carbon dioxide represented by the present carbonates and carbonaceous deposits"[1]. Most of the carbon dioxide that has become available as a source of

carbon is undoubtedly of volcanic origin, being derived from magma.

A useful estimate of the amount of carbon that has been extracted from the atmosphere by various means has been made by Poole[2], who, however, has unnecessarily revived the theory that this has been all present at one time in gaseous combination in a 'primitive' atmosphere. Poole assumes that some of the fixed carbon has been derived from methane so present instead of from carbon dioxide—an assumption he has considered necessary because of an apparent over-supply of the by-product oxygen if carbon dioxide were the sole (or greatly predominant) source of carbon. When, however, oxidation of juvenile hydrogen throughout the long history of volcanic activity is taken into account, there is no longer any difficulty in accounting for the disposal of such an apparent surplus of atmospheric oxygen. A supply of oxygen for this purpose must indeed be found if there is anything of value in the theory of the volcanic furnace. It is permissible, and indeed necessary, therefore, to recalculate Poole's estimate of atmospheric methane as carbon dioxide, a more likely atmospheric gas.

When this is done, the total mass of carbon dioxide is $7 \cdot 02 \times 10^{16}$ metric tons; and to this must be added $0 \cdot 4 \times 10^{16}$ metric tons of nitrogen now in the atmosphere, and also $0 \cdot 18 \times 10^{16}$ metric tons of juvenile hydrogen which has combined with the surplus of oxygen liberated from carbon dioxide, giving a total of $7 \cdot 6 \times 10^{16}$ metric tons of gases in what must be regarded as the primitive atmosphere (itself perhaps very scanty) *together with the gases that have been emitted from volcanoes throughout the history of the earth*. This excludes juvenile water vapour, which it is impossible to estimate by this method; it has undoubtedly made a substantial contribution to the ocean, however. For comparison, the mass of the atmosphere at present, as given by Poole, is $0 \cdot 52 \times 10^{16}$ metric tons.

One great advantage of recognition of the juvenile (magmatic) origin of carbon, as compared with the 'primitive atmosphere' theory, is that it is in agreement with the geological doctrine of uniformitarianism. If one is to understand that doctrine in a forward-looking sense, a continuance of the supply of carbon from volcanoes will make possible the accumulation of further deposits of coal and limestone in the thousands of millions of years of future geological time; whereas in accordance with the 'primitive atmosphere' theory the supply of carbon for this purpose is exhausted, geological processes have worked themselves to a standstill, and we have arrived at the end of the world.

## The Deflexion of Light and Relativity

IN a recent paper, E. F. Freundlich and W. Ledermann[1] have pointed out that "the question remains unsettled whether the light deflection at the sun's limb amounts to $1 \cdot 75''$ as predicted by the Theory of Relativity or whether it is substantially larger, namely, equal to $2 \cdot 2''$ as indicated by the findings of the Potsdam Expedition of 1929 and confirmed by a renewed discussion of previous observational material". The authors then proceed to discuss how an experiment can be planned to settle the question so that the standard deviation of the final result does not exceed $0 \cdot 1''$.

If $m$ is the solar mass and $R$ the radius in natural units, $4m/R$ is the predicted deflexion[2]. But $2 \cdot 2''$ means $5m/R$. As the deflexion provides a crucial test of the theory, the question that is often asked is whether relativity must be modified to give the result $5m/R$ instead of $4m/R$. It is well known that the Newtonian result, $2m/R$, is obtained from the usual equation,

$$\frac{d^2u}{d\varphi^2} + u = \frac{m}{h^2}; \tag{1}$$

and the relativistic result from

$$\frac{d^2u}{d\varphi^2} + u = 3mu^2. \tag{2}$$

For particles moving *almost* with the velocity of light, we have

$$\frac{d^2u}{d\varphi^2} + u = \frac{m}{h^2} + 3mu^2, \tag{3}$$

and the deflexion, small as it is, is

$$\frac{2m}{Rv_0^2} + \frac{4m}{R}, \tag{4}$$

where $v_0$ is the velocity, $Rd\varphi/ds$, at the perihelion. For light $v_0 = \infty$. The range $1 \leqslant v_0 \leqslant \infty$ corresponds to the velocity $Rd\varphi/dt$ lying between $0 \cdot 70c$ and $c$. The deflexion is $5m/R$ for a particle for which $v_0 = \sqrt{2}$ and $Rd\varphi/dt$ is $0 \cdot 82c$. In the Newtonian theory there is no distinction between $dt$ and $ds$, and hence $v_0 = 1$ for light, but the second term of (4), which is of relativistic origin, is absent.

If the deflexion is really $2 \cdot 2''$, one wonders if fast moving atomic particles, with velocities of the order of $0 \cdot 8c$, participate in the process leading to the observed result.

## The Commutation of Annual Subscriptions

MOST learned societies allow future annual subscriptions to be commuted by single payments which range from five to twenty-five times the annual subscription with, in many cases, a reduction to members of long standing. Although this is usually advantageous to the younger members, it is too expensive at later ages when there is most interest in commutation. There has thus arisen a growing demand for commutation scales on an actuarial basis.

Some examples of such scales may be given. The Institute of Actuaries, with an annual subscription of 3 guineas ceasing at the age of seventy, requires a payment of 30 guineas at age forty-five, with 1 guinea less for each additional year of age up to sixty and then by steps of $1\frac{1}{2}$ guineas to a minimum of $7\frac{1}{2}$ guineas at sixty-five and over. The actuarial basis of this scale is not stated, but the amounts appear to be two thirds of those derived from a $3\frac{1}{2}$ per cent annuity table.

The Royal Society now permits commutation on payment of the amount which the fellow would have to pay for a Government annuity on his own life

of the amount of the annual subscription. This varies with the price of $2\frac{1}{2}$ per cent Consols and the basis is a very stringent one, since the amounts payable are those required if fellows had entered into agreements to continue their annual subscriptions for the remainder of their lives.

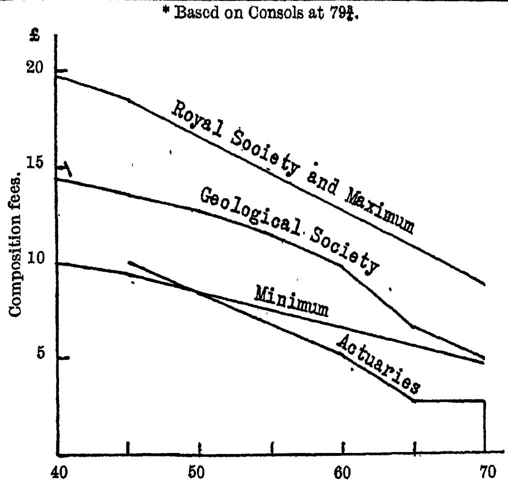
The most elaborate scale is that of the Geological Society of London. The full table contains some thousands of entries; it quotes the commutation fee for each age *at election* from twenty to eighty, combined with each number of annual contributions already paid, from nought to fifty. It does not seem to have been noticed that, in general, age at election plus number of annual contributions already paid equals present age. Apart from a few unnecessary irregularities, the vast table could be replaced by its top line with "age last birthday" substituted for "age at election" or by its first column.

The commutation scales of these societies for ages forty to seventy, all expressed as per £1 of annual subscription, are summarized in the accompanying table and graph, which also give suggested maximum and minimum scales. The maximum scale, which on the graph can scarcely be shown separately from that of the Royal Society, is based on the Mortality of Annuitants, 1900–1920, $a(m)$ 3% Ultimate.

COMMUTATION FEES PER £1 OF ANNUAL SUBSCRIPTION £

| | Age last birthday | | | | | | |
|---|---|---|---|---|---|---|---|
| | 40 | 45 | 50 | 55 | 60 | 65 | 70 |
| Institute of Actuaries | — | 10·0 | 8·3 | 6·7 | 5·0 | 2·5 | Nil |
| Royal Society* | 19·8 | 18·2 | 16·4 | 14·4 | 12·4 | 10·4 | 8·5 |
| Geological Society | 14·3 | 13·5 | 12·7 | 11·1 | 9·5 | 6·3 | 4·8 |
| Suggested maxima | 20·1 | 18·4 | 16·7 | 14·8 | 12·9 | 10·9 | 9·1 |
| Suggested minima | 10·0 | 9·2 | 8·3 | 7·4 | 6·4 | 5·5 | 4·5 |

* Based on Consols at $79\frac{1}{2}$.



Age last birthday (years).

Any society which wishes to institute a scale of commutation fees should, I think, take into account the normal rate of withdrawal from its ranks. The suggested maximum scale, which assumes that withdrawals are impossible, will rarely, if ever, be applicable, and in general some percentage of the maximum should be used. Where withdrawals are rare, the percentage should be nearly 100 per cent, but where withdrawals are more frequent, as in societies the members of which are loosely held together only by a common interest in some field of activity, a lower percentage should be used. It is suggested 50 per cent of the maximum should be regarded as the minimum. Women should pay slightly higher commutation fees, but most societies will ignore this. In selecting a scale, simplicity is more important than adherence to exact actuarial values; in most cases either a single arithmetical progression or possibly two, as used by the Institute of Actuaries, will suffice. Thus the minimum commutation scale for a society with an annual subscription of 5 guineas might be 70 guineas at age twenty-five and decrease by one guinea for each additional year of age to a minimum of 20 guineas at age seventy-five.

What should be done with such commutation fees? Most societies invest the whole of them and transfer to ordinary income only the interest earned; they thus build up useful hidden reserves in their accounts. Some further transfer to ordinary income is, however, reasonable and, in the absence of periodical actuarial investigation, it will in the long run be found satisfactory to transfer to ordinary income, in addition to the interest earned on the commutation fee fund, some small portion of each commutation fee received. This may be, say, one sixth, or alternatively the amount of one annual subscription. Only the balance of each commutation fee would then be invested.

DAVID HERON.

## Mr. W. L. Sclater

MANY years after his friends—Dr. A. C. Stark, the brothers H. F. and W. Francis and F. C. Selous—had lost their lives by enemy action, W. L. Sclater also fell a victim to enemy action[1]. Sclater was director of the South African Museum from 1896 to 1906. He was appointed director when the new building (the present one) had just been completed, and his was the task of planning the arrangement of the exhibits. In the main his original plan persists, though with the logical alterations and extensions made possible by the addition of a new wing in recent years.

The late Dr. Peringuey was already on the Museum staff as entomologist. Sclater proceeded to assemble, as members of the staff or as honorary curators, a body of scientific workers to undertake research on the Museum collections: the late Dr. W. F. Purcell for invertebrates, the late Dr. Gilchrist for marine biology, the late Dr. Corstorphine for geology, and afterwards Dr. Rogers (happily still with us), and the late Dr. Pearson for botany; he himself took charge of the vertebrates. The acquisition of specimens was extended and accelerated by regular museum correspondents in all parts of the country, and the collections grew at a pace which has scarcely been exceeded in recent years, except in the various groups of invertebrates, even with the Museum's increased staff and facilities for field work.

To him was due the appointment of a promising young taxidermist, Mr. J. Drury of Perth, whose talents reached full fruition only after Sclater had resigned the directorship, and resulted in the unique series of casts of living Bushmen.

# OCCASIONAL WHITENESS OF THE DEAD SEA

By DR. R. BLOCH and H. Z. LITTMAN
Palestine Potash, Ltd., Jerusalem
and DR. B. ELAZARI-VOLCANI
Daniel Sieff Research Institute, Rehovoth

ON the morning of August 25, 1943, it was observed that the whole Dead Sea, which at this season is always perfectly clear, had become milky white. The same observation was made on the same morning at the northern and southern ends, which are seventy kilometres apart, and it was further ascertained that during that night the whole Dead Sea had turned white. During winter storms a seam of some 100 metres occurs frequently along the shores, turbid and yellowish, but it was never observed that the whole Dead Sea surface had turned white. The turbidity gradually disappeared and in December 1943 the water became almost clear again.

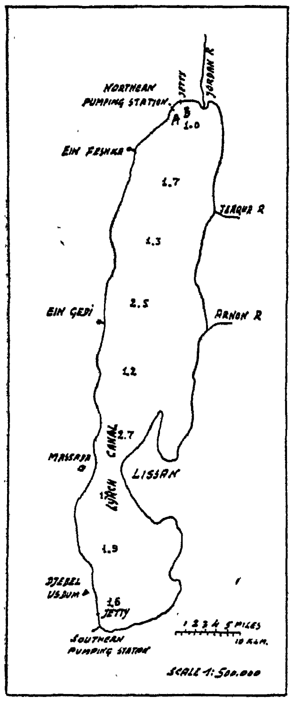

Fig. 1. MAP OF THE DEAD SEA, SHOWING THE RELATIVE TURBIDITY OF THE SURFACE LAYER.

The nephelometric analysis of several water samples taken on October 10, 1943, revealed the distribution of the turbidity as shown in the map (Fig. 1). The numbers represent the relative turbidity, the lowest value taken as unity. Samples at different depths taken at point *A* in the map showed the following relative turbidity:

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Depth in metres | .. | 0 | 2 | 3 | 5 | 10 | 15 | 20 | 50 |
| Relative turbidity | .. | 1·3 | 1·2 | 1·1 | 1·5 | 1·9 | 1·1 | $<$1 | clear |

A sample of 30 litres was taken at place *B* and filtered. It contained 0·018 gm./litre of a white solid of which 15 per cent was insoluble in diluted hydrochloric acid, 5 per cent was insoluble in concentrated hydrochloric acid, and 80 per cent was calcium carbonate. Moreover, the turbidity of other samples dissolved readily on adding hydrochloric acid, developing carbon dioxide.

On a rough calculation, one million tons of calcium carbonate seem to have spread over the whole Dead Sea during the night. There is no obvious explanation for this phenomenon. There was only the usual slight wind blowing from both the northern and southern shores towards the centre of the Sea. No earthquake was registered before or after the night in question, and the occurrence of a slight tremor 12 and 16 days later (September 6 and 10) offers no explanation. Dr. M. R. Madwar, director of the Helwan Observatory, Egypt, informs us that no other nearby earthquakes were recorded.

We inquired, therefore, whether the phenomenon which we had witnessed had ever been observed before. The Dead Sea has been under close observation since 1921, when Mr. M. Novomejsky, the founder and managing director of the Palestine Potash Ltd., started his experimental installations and observation posts. During this period no such phenomenon is known to have occurred. In the nineteenth and the early twentieth centuries several scientific men visited the Dead Sea but none of them (Schubert, Russegger, Robinson, Wilson, Welcotts, Seetzen, Castigan, Scott, Molineux, Lynch, Larter, Blanckenhorn) has ever said anything about the Dead Sea being white. When at our suggestion a preliminary survey of Hellenistic literature was made, a quotation from the famous Greek physician Galen, who visited the Dead Sea at about A.D. 158, was found* in his "De Simplicium Medicamentorum Facultatibus"[1], stating that the waters of the Dead Sea "appear at first glance whiter and heavier than all Seas". (το δὲ τῆς ἐν Παλαστίνῃ Συρίᾳ λίμνης ὕδωρ, ἥν ονομάξονσιν οἱ μὲν θάλασσαν νεκράν, οἱ δε λίμνην ἀσφαλτῖτιν . . . κατὰ τὴν ὄψιν εὐθυς ἅμα πάσης θαλάσσης λευκότερον τὲ καὶ παχύτερον φαίνεται.)

As the purpose of Galen's journey was to establish the usefulness of its waters for the preparation of drugs, he must have surely meant that the water itself was white, and not the appearance of the sea at certain hours of the day as Russegger[2] described it in 1815. Thus Galen appears to be so far the only reliable investigator who mentions the Dead Sea as being white, although this place was repeatedly described during the Roman occupation of Palestine. In this connexion it may be worth mentioning that in the Bible (*Genesis*, 14, 3) the sentence occurs: ". . . in the vale of Siddim, which is the salt sea". The word "Siddim" has no connexion with "Sodom", the Hebrew spelling of which is quite different, but could be the plural of the Hebrew "Sid", which means lime. If that be an indication that the Dead Sea was white in Abraham's time, then the following observation might lead to some better knowledge of Biblical times.

We have seen that human records have very little to tell about this outstanding event in the history of the Dead Sea. But we have found much more in the books of Nature.

One of us[3] obtained during December 1941 from the bed of the Dead Sea a number of profiles 10–170 cm. long, from depths varying from 70–330 metres and taken at different places. On dissecting the longest profile a 'spectrum' of layers of different colours—black, dark-blue, grey, brown and white—was revealed.

* Flusser, Hebrew University, Jerusalem, private communication.

The thickness of the distinct white layers is 0·3–6 mm. It is interesting to note that the white zones of sediment form no seasonal repeat pattern. The following table shows the result of analyses of the dry substance of two white layers (Nos. 1 and 2) and of some dark material (No. 3); these were made two years after taking the profile.

| No. | 1 | 2 | 3 |
|---|---|---|---|
| Distance from top of profile (cm.) .. | 38 | 52 | 53–58 |
| Calcium carbonate (per cent) .. .. | 70 | 81 | 38 |
| Insoluble in hydrochloric acid (per cent) | 7 | 3 | 35 |

The identity of colour and chemical composition of the white layers with the material causing the turbidity is striking. We therefore assume that each white layer of the Dead Sea bed is caused by an outbreak of turbidity, and that similar outbreaks occurred earlier and are distinctly recorded on the profile. The dark layers, containing much more silicates, are formed by the mineral materials brought annually into the Dead Sea during the normal periods between outbreaks of turbidity. Hence, an exceptional opportunity is thereby offered to investigate the history of the Dead Sea chronologically, and to detect the time of similar 'blanchings' in history by fixing the thickness of the annual dark sedimentation which settles on the 'white lawn' that has formed during the last outbreak.

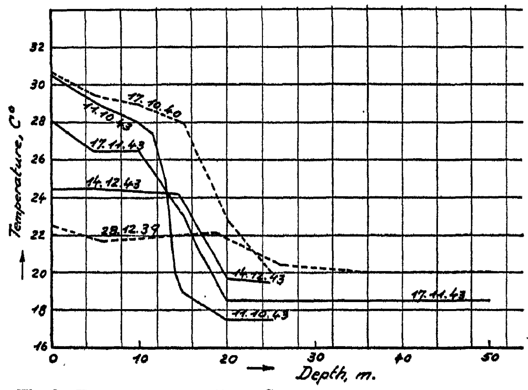

Fig. 2. TEMPERATURE OF DEAD SEA WATER AT DIFFERENT DEPTHS AND TIMES.

Another phenomenon connected with the spontaneous occurrence of turbidity is the change in temperature which took place in the Dead Sea water. It has been assumed that the white colour of the surface water must cause a rise in reflexion of the sun's rays. The assumption was confirmed by measurements of temperature at different depths, which are represented in Fig. 2. We find a difference of as much as 8° C. in October 1943 as compared with October 1940, at the depth of 15 m. below the surface. It is noteworthy that the temperature of deeper strata rose again when the turbidity slowly disappeared. This occurred in spite of the fact that the temperature nearer the surface was then lower owing to the progressing winter season. It is therefore most probable that the lower temperature in 1943 was not caused by fluctuation of atmospheric temperature but by the stronger reflexion of the sun's rays.

It may also be assumed that the lower temperature has caused a corresponding reduction of evaporation, but measurements of the sea-level gave no clear picture, because the quantity of rainfall during the preceding winter season was exceptionally large and evaporation during the first month of 1943 was low. It may, however, be possible to find later on the correlation between the rise of sea-level and the 'blanching' of the Dead Sea and thereby to determine the sea-levels which existed in the past.

We have, of course, tried many explanations for the phenomenon described, but none of them is as yet well enough founded to be of sufficient general interest. Owing to war time conditions, it was unfortunately not possible to make more exhaustive observations and measurements, but it is hoped to clarify some time later the various questions by systematic borings of the Dead Sea bed, and by a careful study of the ancient literature on Palestine and the Dead Sea. We hope that the results will not only be important from geological or even technical aspects, in affording an exact knowledge of sea-levels at different times, but also for students of history and of the Bible, since there is a close link between the Dead Sea and the development of religion.

We wish to extend our thanks to the managing director of the Palestine Potash Ltd., Mr. M. Novomejsky, and to those of the Company's staff, who were helpful with suggestions and measurements, especially to Messrs. Campbell, Cahaner, Shirisly and Schnerb.

# INDIAN UNIVERSITY ARCHITECTURE

IN a paper read before the Indian Institute of Architects early this year, Nawab Zain Yar Jung Bahadur, chief architect, Hyderabad State, dealt with the design of a residential university, as exemplified in the new Osmania University in Hyderabad. This has been planned on the American campus principle on a site of 1,600 acres, giving ample space for future expansion and the inclusion of well laid-out grounds of impressive dimensions. The author had previously made a fairly thorough study of university architecture both in Europe and the United States, in which connexion he expressed pleasure at the evidence of a master plan in the design of the English universities of Birmingham and Nottingham, but regrets that it is less evident in the case of Edinburgh and Leeds and in most of the Indian universities.

The Osmania University is located in somewhat hilly and picturesque country at Adigmet, a village between Hyderabad and Secunderabad to the north-east of the city, nearly 200 ft. above the level of the city, of which it commands beautiful views. Among the ridges on which the University is being built the highest has been set apart for the senate hall, which is to be a monumental building and the keystone of the whole project. On one side of it is the arts college, already completed, and on the other the library and law college will be built. These will form the central group of the main axis. There are two ridges stretching from the senate hall hill: on the left ridge all the science colleges are or will be located, three of which—physics, chemistry, and biology—are already under construction. The ridge to the right has been reserved for the museum and the training college, the training school, the school of arts and the art gallery. The hostels and dining halls are situated in the loop behind the science

colleges, and the residential area for the teaching staff is beyond the hostels.

In addition to these, sites have been selected for the medical college and hospital, the colleges of agriculture and forestry, the college for women, a students union, a faculty club, a market, a post and telegraph office, botanical garden, stadium, gymnasium, swimming pool, and a colony for subordinates and servants. It is interesting to note, in regard to acoustics, that only large lecture theatres have been given acoustical treatment, and only those rooms where quiet is absolutely essential, owing to the heavy cost of acoustic materials.

One of the main causes of disease in India is said to be the impurity of drinking water; and the question of having separate drinking water for caste Hindus is also a problem for schools and colleges which cannot be ignored. To meet fully the special needs in this respect and minimize risk of infectious disease, modern drinking fountains are being installed throughout.

In regard to style, the author said that in other important countries of the world the science of architecture has made rapid progress, but in India he thinks they are sadly behind the times; and in spite of the money that has been and is being spent on educational institutions, he has seen nothing yet of real architectural value. "In fact some of the buildings are so poorly designed and so badly constructed that they are a blot on the landscape and invoke in the heart an unholy desire to pray for an earthquake or fire." The reigning Nizam, who has taken a keen interest in the new University, expressed the wish that, while possessing all modern facilities, it should have no Western elements in its architecture. Speaking of the arts college at the time of his Jubilee, His Exalted Highness said that "the architecture of this building represents a blending of the Hindu and Muslim styles, and the art and culture of both these races are reflected in the pillars and traceries and carvings on the doors and walls. Thus the building symbolises the close contacts and friendly relations subsisting for centuries between the various classes of my subjects. . . . The Osmania University should not only be a repository of Hyderabad's best traditions, a model of its high culture; it should also aim at broadmindedness and mutual toleration and unity among the students, for in that ideal lies the well-being and the prosperity of this State".

The author has accordingly embodied the Hindu and Muslim cultural elements of all periods in the State, such as the Buddhist, Jain, Brahmanic, Bahmani, Kutub Shahi and Moghal. These have all been blended to form a composite whole, signifying the evolution of a new style which should distinguish His Exalted Highness's reign from all the other rulers in the history of the Asafjahi dynasty.

The arts college which, at the beginning of this year, was the only completed building in the scheme, covers an area of 250,000 sq. ft. and is designed to accommodate two thousand students. It is a two-storied structure, with basement, built entirely of local granite of pink and grey shades, with the inner walls plastered and the outer surface in ashlar masonry. All the rooms are finished in plain white lime plaster, except the entrance hall, where stucco is used. The dome surmounting the entrance hall is about 50 ft. in diameter, resting on corbel slabs. The entrance hall is built in reinforced cement concrete, and is 66 ft. from floor to ceiling. The main roof and intermediate floors and staircases are constructed in reinforced cement concrete. All the floors are paved with polished Shahabad stones from the regions of Tandur and Nawandgi in Hyderabad State, with the exception of the entrance hall, where the floor is red terrazzo. The most difficult and slow part of the work was the process of stone-dressing, as the local granite is of the hardest variety. The stone lintels over the massive columns of the ground floor verandah of the arts college weigh about seven tons each and are 18 in. in span. The stones used for the decorative cornices weigh 2½–3¾ tons each. The complete woodwork (including furniture) of the entire buildings is being carried out in the best Rangoon teak. 4,000–5,000 workmen were engaged during the first year or two of the construction work. In addition to local labour many stone-dressers and artisans were imported from southern towns such as Tanjore, Turkapalam and the Conjivaram, to assist directly with the work and also to train the local workers.

The whole scheme is expected to cost a little over two crores, and the author replies to some criticism on the ground that far too much money is being expended on the new University. Before he had seen some of the world's greatest educational centres he was inclined to agree that the cost should be kept low; but examples in other parts of the world convinced him that the University is a nation-building institution in the best sense of the term; the future of the younger generations and of the State itself will obviously depend on the type of University. It is concluded that if the people of India are to be brought physically and mentally to the same level as those of other civilized nations, it is vital that the new University, and others in India, should be built on the principles accepted and the standards fixed in other countries; and it is quite certain that Hyderabad is a big enough State to think of a big university worthy of itself and of its traditions.

## EAST AFRICAN ARCHÆOLOGY

FIVE distinct types of polished stone axe have been recognized in East Africa. Most of the specimens found were pecked and not ground into shape before being finally polished. No geographical significance can be attached to any of the five types; their distribution will probably be found to be very wide, though for the moment for obvious reasons they have mostly turned up where European settlement involving farming has taken place. A description of the various types, together with a list of some of the localities where they have been found, has been made available in a collection of reprints recently received*. A general sketch map, too, is appended. Finally, a short note on the occurrence of the different types outside East Africa concludes the article.

Gorgora, on Lake Tana, was a former Italian military station. The rock-shelter is situated some 150 ft. up in the side of a conical hill of volcanic rock which rises abruptly from the plain some three miles from the Lake. The shelter is most inaccessible and can only be approached from one direction. It is some 15 ft. long by 8 ft. at the widest. Black soil rich in humus was found from the surface to a depth

* "Notes on the Ground and Polished Stone Axes of East Africa", by Mary D. Leakey; "Excavations of a Rock-Shelter at Gorgora, Lake Tana, Ethiopia", by Colonel F. Moysey; "The Industries of the Gorgora Rock-Shelter, Lake Tana", by L. S. B. Leakey. Reprints of the *Journal of the East Africa and Uganda Natural History Society*, 17, Nos. 3 and 4 (77 and 78), 182–203.

of 4 ft.; then to the 9-ft. level there was a grey volcanic ash. At this level, concretions appeared, and these formations increased down to the 12-ft. level. Implements occurred throughout the deposits, and pottery was found to a depth of 3 ft. from the surface. There were no sterile layers.

Dr. Leakey's analysis shows that the industries of the 12-, 11- and 10-ft. levels can be classified as Early Stillbay; those from the 9-, 8- and 7-ft. levels as Middle Stillbay; those from the 6-, 5- and 4-ft. levels as Upper Stillbay; those from the 3-ft. level as Magosian; those from the top 2 ft. of deposit as late Mesolithic or Neolithic. This industry includes some crude microliths, and appears to be derived from the earlier Magosian. A few simply decorated sherds were also discovered in this level. The industries from the older levels are fairly typical, but the 4-ft. level gives us a transition stage between the latest Stillbay and the Magosian. An analysis of the different types of artefact found is given, and the article is well illustrated.

The rock-shelter at Gorgora is obviously of some importance. Such transition industries as those of the top 2 ft. and the 4-ft. level are very interesting. The excavations are not yet completely concluded, and it is to be hoped that further investigations at this site and elsewhere in the neighbourhood will be undertaken at a not too distant date.

M. C. BURKITT.

## QUARTZ CRYSTAL MODEL

DIFFERENT types of deformation extend the range of frequencies that quartz plates can cover and a single plate may be used for totally different ranges when made to vibrate in different modes. To obtain most of these various modes of vibration the plates must be cut from the mother quartz at different angles with respect to the electrical, mechanical and optical axes of the quartz crystal. There are also special orientations which provide better frequency stability in cases of temperature changes, and these orientations are used where stringent temperature requirements apply.

A recent interesting article by F. Caroselli (*Bell Lab. Rec.*, **22**, No. 9; May 1944) describes and illustrates a large fabricated model of a quartz crystal, employed for showing more clearly the angular relations of the various cuts of plates to the original mother crystal. The model has an outer shell about two feet high that shows the typical shape of quartz as it grows in Nature, and an inner display of crystal plates. The shell and display tiers are made of sheet lucite and the plates are lucite, roughened to appear like etched quartz. The plates include those used for oscillators and filters.

About the vertical axis the outer shell shows an array of faces that repeat three times in exact symmetry. This is the optical axis, and it is the only direction through quartz along which a light ray will travel without dividing into two rays of different velocities which are refracted by different amounts. The shell can be rotated with respect to the inner display so that its faces can assume three identical orientations with respect to the crystal plates. Three pairs of $X$ and $Y$ axes are marked on the apron of the model to demonstrate the trigonal symmetry of quartz.

Before constructing the outer shell of the model, formulæ were developed from published crystallographic data to compute the angles between adjacent faces. All identical faces were made the same size by having the major apex faces meet in the vertical axis of the model. Minor apex faces were located at an arbitrary distance from this central axis.

The model illustrates cuts used in ranges varying from less than 1 kc. to 24,000 kc., and each one is particularly suited for a definite range of frequency. In addition, there are several different cuts operating over the same range but having some specific characteristic. On the top tier of the display there is a plate the coating of which is divided so that it will vibrate by flexing the major surfaces; and on the bottom tier are a number of plates of the same cut but with the coating divided to excite the third, the fifth or seventh harmonics of a longitudinal mode of vibration.

## COLOUR TELEVISION

A DEMONSTRATION was given a short time ago by Mr. J. L. Baird of his recent achievements of the reception of television in colour by a method which avoids the need for revolving disks and lenses; the apparatus is thus silent in operation and is claimed to be as efficient as the pre-war black-and-white receivers. The pictures in colour are also utilized to produce stereoscopic effects by the use of coloured viewing glasses, the left and right eye pictures corresponding to the left and right eye images.

For the reproduction of the received pictures a special cathode ray tube, termed a 'Telechrome', is used; this differs from the ordinary tube in having two cathode ray beams and a transparent double-sided screen. These two cathode ray beams are modulated by the incoming signals corresponding to the two primary colour pictures; and they impinge obliquely on opposite sides of the screen, these sides being coated with fluorescent powders of the appropriate colours. Thus the screen has formed upon its front face an image containing the orange-red colour components, and on its back face an image containing the blue-green components. When the screen is viewed normally from the front, these images are superimposed and thus give a picture in natural colour.

Such a two-sided tube has been developed with a screen, 10 in. in diameter, and was shown receiving a picture from a 600-line triple interlaced moving spot transmitter using a cathode ray tube in combination with a revolving disk with orange-red and blue-green filters. The tube gives a very bright picture due to the absence of colour filters and the fact that special powders are used giving only the desired colours, which are seen additively.

A method of using three colours has also been described in a patent specification. In this case, the back of the screen is ridged: the two sets of faces of the ridges are coated with blue and green powders respectively; and they are scanned by two cathode ray beams, modulated by the blue and green components respectively, of the incoming signals. The third beam, carrying the red picture components, impinges on the front of the screen as before. A new form of scanning is also being explored, using successive lines of different colour, with the object of reducing the colour flicker which is obtained when, as at present, the colour changes are by frame to frame only.

# FORTHCOMING EVENTS

### Saturday, September 23

BRITISH PSYCHOLOGICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Prof. J. C. Flugel: "Psychological Aspects of Moral and Social Progress" (Papers in comment by Dr. Karl Mannheim and Dr. R. H. Thouless).

### Tuesday, September 26

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Dr. S. C. Bradford: "Some General Principles of Bibliographical Classification, with application to the Universal Decimal Classification"; Mr. C. L. Gilbert and Mr. C. G. Gray: "The Classification of Literature in the Technical Department of an Oil Company".

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Mr. T. Thorne Baker: "Some Uses of Dried Emulsions in Photographic Industries", with a Demonstration of Silk Screen Printing.

### Wednesday, September 27

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Mr. L. C. Southcott and Mr. D. W. Rudorff: "Superheaters for Water Tube Boilers".

### Friday, September 29

BIOCHEMICAL SOCIETY (in the Department of Biochemistry, The University, Western Bank, Sheffield), at 11 a.m.—The 236th Meeting.

ROYAL INSTITUTE OF CHEMISTRY (joint meeting of the BIRMINGHAM AND MIDLANDS SECTION with the INSTITUTE OF PHYSICS) (in the Connaught Room, Imperial Hotel, Birmingham), at 6.30 p.m.—Dr. G. W. Scott-Blair: "Rheology of Plastics; Stress-strain-time Relations for High Polymers and Similar Materials".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEPUTY CHIEF ENGINEER—The Borough Electrical Engineer and Manager, Guildhall, Swansea (September 28).

LECTURER (full-time) IN PHYSICS—The Principal, Royal Technical College, Salford (September 29).

CHEMIST to the Tees Valley Water Board—The Engineer and General Manager, Water Board Offices, Corporation Road, Middlesbrough (endorsed 'Chemist') (September 29).

SPEECH THERAPIST—The Director of Education, Shire Hall, Nottingham (September 30).

GRADUATE ASSISTANT MASTER IN ENGINEERING—The Principal, South Dorset Technical College, Newstead Road, Weymouth (September 30).

SPEECH THERAPIST—The Director of Education, Stanley Buildings, Caunce Street, Blackpool (September 30).

CHAIR OF PHYSIOLOGY in the University of Ceylon—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 30).

CHAIR OF ELECTRICAL ENGINEERING—The Acting Registrar, The University, Leeds 2 (September 30).

CHAIR OF BIOLOGY in Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (September 30).

PRINCIPAL OF THE HACKNEY TECHNICAL INSTITUTE, and PRINCIPAL OF THE SOUTH-EAST LONDON TECHNICAL INSTITUTE—The Education Officer (T.1), County Hall, Westminster Bridge, London, S.E.1 (September 30).

PRINCIPAL OF THE WALKER TECHNICAL COLLEGE, Oakengates—The Secretary for Education, County Buildings, Shrewsbury, Shropshire (September 30).

TECHNICAL ASSISTANT FOR LABORATORY attached to Engineering Firm (N.W. London district)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2278.XA) (October 2).

PHYSICIST OR ENGINEER, B.Sc. Grade, for scientific instrument development work (Oxford area)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.584.XA) (October 2).

ENGINEER AND GENERAL MANAGER to the New Zealand Hutt Valley Electric Power Board—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.931.A) (October 7).

EXAMINING OFFICERS (temporary) IN THE PATENTS OFFICE (candidates should have a University Degree (or equivalent) in Science or Technology with Chemistry as a subject)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2982.A) (October 9).

PROFESSOR OF PHYSICS—The Registrar, University College, Singleton Park, Swansea (October 18).

HONOURS GRADUATE IN CHEMISTRY (London, Reference No. F.2719.XA), HONOURS GRADUATES (2) IN METALLURGY (Neath, Reference No. F.2720.XA; Shipley, Reference No. F.2721.XA), and HONOURS GRADUATE IN CHEMISTRY or Member of the Royal Institute of Chemistry, Branch E (London, Reference No. F.2722.XA), on the research staff of a progressive National Organization with home and overseas interests—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (October 21).

QUALIFIED CHEMIST with some research and industrial experience, by a progressive concern in the Spen Valley district of Yorkshire—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.1737.XA) (October 27).

LIBRARIAN—The Librarian, Queen's University, Belfast (October 31).

CHAIR OF PSYCHOLOGY in the University of Sydney—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (October 31).

BEYER CHAIR OF ENGINEERING—The Registrar, The University, Manchester 13 (November 18).

PROFESSORSHIP OF NAVAL ARCHITECTURE, tenable at King's College, Newcastle-upon-Tyne—The Acting Registrar, University Offices, 46 North Bailey, Durham (November 30).

FELLOWSHIP AND TUTORSHIP IN MATHEMATICS—The Senior Tutor, Jesus College, Oxford (December 1).

SPEECH THERAPIST—The Director of Education, Education Office, Rotherham.

LECTURER (woman, temporary) IN PSYCHOLOGY AND PRINCIPLES OF EDUCATION in the Glamorgan Training College, Barry—The Director of Education, Glamorgan County Hall, Cardiff.

LECTURER (full-time, temporary, man or woman) IN BIOLOGY in the Leeds College of Technology—The Director of Education, Education Offices, Leeds 1.

ASSISTANT HEAD OF THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Principal, Birmingham Central Technical College, Suffolk Street, Birmingham 1.

AGRICULTURAL ENGINEER (for London), with practical knowledge of Drainage and Irrigation—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. R.S.70).

CHAIR OF OBSTETRICS AND GYNAECOLOGY in the Royal Faculty of Medicine, Baghdad, Iraq—Appointments Department, British Council, 3 Hanover Street, London, W.1.

SPECIALIST (for London), with general all-round knowledge of Food Processing of Milk, Dairy Products, Meat, Vegetable Fats and Oils, Fish, etc.—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. R.S.66).

LECTURER (full-time, temporary) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

PAPER MILL ENGINEER for Bengal, with practical Paper Mill experience, capable ultimately of taking charge of all Papermaking Plant Maintenance—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. O.S.228).

ASSISTANT LECTURER IN AGRICULTURAL ZOOLOGY—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

SECOND VETERINARY OFFICER, Imperial Bureau of Animal Health, Weybridge—The Secretary, Imperial Agricultural Bureaux, 2 Queen Anne's Gate Buildings, London, S.W.1.

# SCIENTIFIC AND INDUSTRIAL RESEARCH.—VI

WE have now completed our survey of the strategy and tactics of research in respect of the workers and organization required, and the broad objectives of programmes to serve the advance of science and the needs of the nation. We have now to view in conclusion, more from outside, the structure thus adumbrated; and to consider, not primarily the service to be rendered thus to the community, but the price that must be exacted from the community in order that such an organization may function effectively and render the services set forth. That support has two main aspects: financial and educational. Research in any field cannot be prosecuted effectively unless support is forthcoming on an adequate scale. Such support in turn is unlikely to be forthcoming unless the reasons for prosecuting research are adequately understood by the public; and once again, the case for research is unlikely to be presented effectively unless the possibilities are fully appreciated by the administrator, whether he be in Government service or in industry.

For our present purpose it is unnecessary to enlarge on the financial aspect. Estimates as to the cost of the programmes and of the organization involved are as yet incomplete or tentative. Many of the essential facts have yet to be determined, and even the programmes themselves to be outlined adequately. Sir Ernest Simon has estimated that the necessary expansion and development of the universities involves increasing the Exchequer grant to £4 millions in the first year after the War and successively to £8 millions in the fifth year, with capital grants on the scale of £20 millions over a period of ten years. The Parliamentary and Scientific Committee likewise visualizes an increase of the Treasury grant to six or seven million pounds, with at least £10 millions over the first five post-war years for capital expenditure, and the British Association Committee on Post-War University Education estimates this capital expenditure at £25 millions. The Association of Scientific Workers puts the total university expenditure at about £15 millions after five years and at £20 millions after ten years, most of which will have to come from the State; accordingly, it anticipates an increase in the annual Government grant to £9 millions after five and to £13½ millions after ten years.

This is only a part of the national research budget directly charged on the State, though, of course, a large part of the university expenditure is only indirectly for research purposes. Estimates as to the increased expenditure involved in the research directly financed by the State are fewer, and in any event are at present largely tentative in the absence of the essential surveys or broad programmes. The Parliamentary and Scientific Committee puts the desirable expenditure on coal research alone at "several millions" and on agricultural research at at least three millions per annum. In its statement "A Post-War Policy for Science", the Association of Scientific Workers puts

the cost to the State of the proposed increases at about £18 millions, of which £7 millions would be for industrial research (as against £3 millions pre-war), £6 millions for agricultural advisory services, six hundred thousand for agricultural research, £4 millions for medical research (in place of £2 millions before the War) and half a million for consumer research. Even this estimate takes no account of Colonial research, for which expenditure up to half a million a year has already been provided under the Colonial Development and Welfare Act of 1940, or of the social and economic research adumbrated in the Nuffield College statement and elsewhere.

It is sufficient, however, for the present purpose to note that expenditure ranging up to what might well approach £50 millions can scarcely be appropriated without widespread public understanding of its purposes and implications. It is most important that these calculations should be properly and exhaustively made and that the cost of expansion should be determined and apportioned. But it is even more important, as *The Economist* has pointed out, that in this process the right relation should be devised between the universities and public bodies, including local authorities as well as the central government. That can scarcely be secured unless on one hand the underlying issues are clearly understood by the local authorities, in Parliament and by the electorate, so that decisions are taken free from prejudice or the pressure of private or sectional interests; and on the other, the question of university research and finance is seen as part of, and in relation to, the wider question of the national research effort.

From this point of view, accordingly, it is all-important that in the comprehensive reconstruction of our education system, of which the Education Act embodies the first instalment, the system should be regarded as a whole, from the nursery school to the universities and adult education beyond the university stage. No matter how perfectly our research organization is designed to serve our strategy, embodies the correct tactics and executes the programmes planned, it will only be fully effective when it has the intelligent support of the body of the nation it serves. By this means alone can we be sure, as the history of the last twenty years shows, that no false economy or sudden demand for retrenchment will cripple the long-range plans which would bring immeasurable returns to the nation's balance sheet.

That point of view is clearly recognized by the Government. In admitting the Government's responsibility for giving a lead in this matter of research, the Lord President of the Council, Mr. Attlee, stated in the House of Commons debate that Government support for research must be backed not only by a readiness to use the results of that research, but also by public opinion and by the nation becoming more aware of the importance of science. Mr. Attlee regards the Education Act as an essential means of getting the nation scientifically minded, and stressed that there are three parties: the Government, industry and the general public. Our research effort will not endure unless, as Mr. Attlee said, public opinion is behind it.

No body is doing more in this work of public education than the Parliamentary and Scientific Committee, and Mr. Attlee paid fitting tribute to that work. Such educational work must be carried on outside as well as inside Parliament, and all scientific workers have their own opportunities as well as responsibility for sharing in the task. The Colonial Research Committee, in its first annual report, makes a sound point in emphasizing the importance of actively associating the Colonial peoples, through their Governments, with the planning and guidance of research. This point has an even wider bearing, for it may well be that until we can secure, in Great Britain as well as in the Colonial territories, that the ordinary citizen is associated with the planning of research, at least to the extent of gaining some understanding of its bearing on his everyday life and welfare, we cannot expect the sustained support and endowment of research on the scale now needed.

That task of education cannot be carried out without the wholehearted support and co-operation of scientific workers themselves, on whose shoulders much of the work of exposition and interpretation must necessarily fall. This is particularly true in respect of the special task of educating the administrator as to the potentialities of scientific research. We may indeed hope that further attention to the training of the administrator and manager, as part of our programme of educational reform, will explode the superstition that business and administration cannot be taught in a university, and demonstrate that a university can provide those whose profession is to be industry or business with a three-years discipline in the fundamentals of the problems they will meet in their professional career. Thus we may ultimately provide both industry and Government departments alike with administrators having sufficient scientific background to appreciate the scientific factors in the problems confronting them, and to discharge more adequately and imaginatively such functions as decisions upon research needs and priorities—a long-range task. The immediate problem is that of educating the present generation of administrators, who carry the responsibilities for the decisions that will permit or warp the post-war expansion of research. As Dr. D. R. Pye suggested recently to the London Institute of World Affairs, the primary responsibility of the universities to industry is to supply the qualified men and women, able executives with trained minds and initiative, capable of seizing upon and developing a new idea or a promising new process.

The concern with which the medical profession has viewed the Government proposals for a State medical service is at bottom due to distrust of the administrator. The weaknesses of the Civil servant as summarized in the recent report on "The Training of Civil Servants" . . . "over-devotion to precedent; remoteness from the rest of the community, inaccessibility and faulty handling of the general public; lack of initiative and imagination; ineffective organ-

ization and misuse of manpower; procrastination and unwillingness to take responsibility or to give decisions" . . . may be exaggerated, but undoubtedly exist, and Prof. H. J. Laski is right when he says that the control of research is often in the hands of men with no serious acquaintance with the possibilities of either natural or social sciences. If this situation is to be rectified, the tendency to departmentalism checked, means found for securing that Government departments are aware of the relevance of achievements of scientific men in other countries, and a more youthful outlook and representation achieved in the direction of the relations between the Government and science, scientific workers must translate their concern for professional and intellectual freedom into a sense of social responsibility which issues in both individual and in corporate action.

Dr. D. W. Hill, in his recent book "The Impact and Value of Science", has put his finger on the weak spot: "Until they have learned to express themselves, scientists will continue to be wallflowers at the world's quickstep". The faults are not all on one side. The indifference and even scorn with which scientific workers have treated this task of exposition is every bit as serious as the defects of the administrator already mentioned. As Dr. Hill says, scientific men must learn to write and to speak so that people will listen to them, and will understand and appreciate their efforts. In place of the isolationist and sometimes arrogant attitude to the administrator, scientific workers must adopt a sympathetic and co-operative attitude: they must seek to help, not to dictate. The task of intelligence calls for tact and sympathy and for imagination on both sides. The man of science as well as the administrator needs to be sensitive to opinion.

These factors are as important in the running of our research organization and in the functioning of its information services as lubrication in running a machine, and especially so in dealing with the present situation, when we cannot wait for a reformed educational system to provide us with improved types of experienced administrators. There is, however, another aspect in which educational reform is important to our plans for the expansion of research. The Association of Scientific Workers has pointed to the need for increasing the supply of laboratory technicians in order that we may make full use of even the existing numbers of trained scientific workers. Equally important is the supply of technicians in industry, and no plans for the expansion of applied research which take no account of the facilities for technical education can be expected to fructify.

The dependence of Great Britain's post-war plans on the provision made for technical education has been repeatedly emphasized of late. It is recognized, as the Nuffield College paper points out, that the management of a firm should include men with a sound knowledge of basic scientific principles and methods. The Government and the public should be similarly equipped. Thus, in the long run, the general need is for a spread through the educational system of a sound knowledge of basic scientific principles and method. Sir George Schuster urged in the House of Commons the need for a very great increase in the number of scientifically trained workers and for a very rapid development of all forms of scientific and technical education; and the Government educational programme was strongly criticized from this point of view in the House of Lords. The report of the London Chamber of Commerce on Scientific Industrial Research also recognized the importance of this question of technical education and urged the allocation of a far larger sum for the development of technical colleges than the £100,000 envisaged in the White Paper on Educational Reconstruction. Similarly, the report of the Parliamentary and Scientific Committee directs attention to the need for a great expansion in technical education, for reconsidering the position of the technical institutions with reference to the universities, and to the value of the large number of technical personnel now in the Forces, if suitably trained, on demobilization.

There is a further point stressed in this same report, as well as in that of the London Chamber of Commerce, which has frequently been overlooked. It is essential to find some means of restoring the status of the craftsman or artisan and technician, both in the laboratory and in the works. When all has been said about the necessity for further provision for technical training of the skilled workers and craftsmen which industry will require in growing numbers, to remedy the present inadequate provision for this purpose will not by itself be enough. There is an important body of industrial opinion which holds that the provision of technical education in Great Britain is inadequate and defective primarily because the country undervalues the man who works with his hands, and regards him as socially inferior to the office or professional worker.

To remedy a perverted social attitude is a matter that lies outside the field of education, in the limited sense of that term, and while the scientific worker will urge the importance of adequate provision for the technical training of the craftsman as bearing vitally on industrial efficiency and the effectiveness of our research organization, he cannot fail to note that here again he must accept some responsibility for attempting to reverse that attitude. More might undoubtedly be done by the example of professional associations, and the scientific worker is prone to overlook the influence that his own personal conduct and attitude may have on his fellow citizens and workers. Social attitudes may be reversed less by propaganda than by the quiet pervasive influence of conduct determined by principles firmly held and resolutely but sympathetically and sincerely explained.

It is not only the general public and the administrator who in such ways as these must be educated to understand the needs and possibilities of the situation in order to enable our research organization to function effectively. Reports from the Department of Scientific and Industrial Research have repeatedly stressed the need for more publicity in industry, and for the education of industry, in order to make the work of the research associations, for example, effective. It has become an important function of some research associations to secure the translation of their

results into terms which are easily assimilable by the industry. The task of public relations has acquired a special significance in this respect for securing that industry is research-minded, and both the report of the London Chamber of Commerce and that of the Industrial Research Committee of the Federation of British Industries have directed attention to this point.

The London Chamber of Commerce urges that chambers of commerce, trade associations and industrial federations should give attention to this question of publicity generally, providing information and advice as to the steps to be taken by firms to get specific research done for them and to utilize the research facilities available. It also suggests that the B.B.C., the Press and the cinema should be used to stimulate interest in scientific work and to interpret the results of that work when applied to industry. That was to be one of the functions of the co-ordinating secretariat for industrial research suggested by Dr. P. Dunsheath, and it is one of the main functions of the bureau of industrial research suggested by the Federation of British Industries. This bureau, though supported financially by research associations, independent research laboratories, Government research establishments, universities and others, would be entirely objective in its activities. Among its suggested activities are the publication of a year-book, in which could be included a short description of the achievements of British research and of the facilities available for the prosecution of research, and educational publicity on research.

In addition to advisory functions on research problems, the Federation of British Industries' Committee visualizes such a bureau as possibly creating a liaison between research workers in similar or related fields. Its existence would in the opinion of the Committee increase the research-mindedness of British industry and foster a greater national sense of the importance of the subject and its influence in maintaining national prosperity and well-being. It might indeed assist in imparting to those responsible for management in large or small firms a scientific approach and understanding of their problems, and encourage a readiness to give a high place in business affairs to the claims of scientific research ; though it can never absolve us from the responsibility already indicated of thinking in terms not only of supplying industry with adequate staffs of experienced research workers but also with managements capable of co-operating fruitfully with them.

The importance of establishing some new machinery for such purposes and of providing adequately for the organization of information or intelligence services is clear, but it must not be forgotten that organization by itself is not enough. We have already outlined the kind of organization which may be required to serve the broad strategy of research and to execute the programmes which may be planned to serve the national needs. We have stressed the need for keeping that organization flexible and sensitive, for development in accordance with the experience of the past, for avoiding compartmentalism or departmentalism; and that in our planning the first attention must be given to the supply of the right personnel.

In this matter of securing adequate and sustained support of research and the effective utilization of its results, the question of personnel again comes before organization, but with a different emphasis. Success in such publicity and educational work depends largely on those who carry it on, and here the scientific worker must always have a large, and at the start a major, responsibility. Educational reform is a slow process, and the full effects are only felt after a period of years. The immediate task of educating the general public, the administrator and industry as to what is involved must be done largely by them or not at all ; and if it is not done, our plans for the expansion and development of research are unlikely to go forward.

Scientific workers will not knowingly neglect their responsibilities, great or small, in such matters as the strategy, the planning or the execution of research. There are signs of an increasing concern with questions of tactics and that the professional associations may take wider and more public-spirited views on some of the problems calling for corporate action, to which in the past they have been indifferent. But the majority of scientific workers have scarcely realized the crucial importance of this task of interpretation and exposition involved in the education of the public, which must proceed step by step as our plans for scientific research are developed.

Research organization may be perfectly designed to serve the purposes of our strategy ; research programmes may be comprehensive and well co-ordinated ; but no excellence of administration or tactics can eliminate the dependence of success or failure on the human element. The research worker, too, does not work in a vacuum. He has relations with the Government or administration, with fellow scientific men in other branches of knowledge, with his fellow citizens in industry and elsewhere. Organization can only provide the means for co-operation, but without the determination or desire to co-operate and some sympathetic understanding of other points of view, organization will not function.

The adequate organization and planning of research involves a great partnership in which the scientific man, whether he be research worker or administrator or expositor, must take his place with those engaged in Departments of State, in industry and in a real sense the general public. The special responsibilities which fall on men of science in formulating strategy or planning programmes, in criticizing constructively the strategy, tactics or organization of research, as well as for the actual prosecution of research, must not lead them to overlook this further responsibility. The prosecution and organization of research can in fact only yield their full results when this task of interpretation and exposition—of educating public opinion as to what is required—is discharged with vision, imagination and persistent resolution, and in a spirit of public service which matches the devotion which scientific workers instinctively bring to the quest for truth in the laboratory.

## A NEW ENGLAND NATURALIST

### A Naturalist at Large

By Thomas Barbour. Pp. xii+314. (Boston, Mass.: Little, Brown and Company, 1943.) n.p.

IN the lives of the older naturalists, as of Louis Agassiz when he was young or John Hunter when he grew old, we find examples of quite peculiar happiness. All their labour was for the love of it; they did exactly as they pleased; they shared a carefree corner of the world with the painter and the poet. Dr. Thomas Barbour is one of the last of the old-fashioned naturalists, and it is the same way with him. He confesses, or boasts perhaps, that "he never does anything he don't want to do—not if he can help it"; and in consequence a glow of happiness runs all through his random reminiscences.

Dr. Barbour has been a museum man all his days, first in Boston, then in Salem, and lastly in the great Agassiz Museum in Cambridge, Mass., which he has had charge of for many years. He has the golden gift of friendship. He has known all the naturalists of his time; he has travelled far and wide, and his fellow-naturalists all the world over have a friend in him. He is a famous museum curator. He has added immense collections to the great museum founded by the elder Agassiz and enriched by his son; he knows what to store away and what to exhibit, and how to label a nightingale or an albatross for the instruction and benefit of ordinary unpedantic mankind.

Rumphius and Wallace set him travelling (with his young bride) to the Dutch East Indies, as they have led so many another naturalist on his way. There, in Ternate, he shot the Rajah's own cockatoo (and had "the devil to pay"); and found a wonderful lizard "with a great fanlike sail on its back and tail, like a Permian Pelycosaur in miniature", which Wallace and Max Weber had both failed to discover. He has explored Central America and Mexico, made countless journeys to the West Indies, visited South Africa later on, and brought stories as well as rich collections from them all. He has a fresh boyish enthusiasm for every rare and beautiful creature. A certain mouse from Darien, golden-brown above and pearly white below, is "a veritable gem among mice"; a tiny frog from Trinidad, living up-country in Bromelia flowers, is "a lovely little creature, tiny, but with eyes like jewels"; and a crystal-clear pool in a Cuban cavern holds "fairy shrimps of a most heavenly crimson, with white tips to their appendages as if they had stepped about delicately in white ink". They had been lost and forgotten, since they were seen long before by Felipe Poey, the first great Cuban naturalist. Dr. Barbour is a botanist among many other things, and for many years he has been in charge of the garden at Soledad, in Cuba, which belongs to Harvard University, and is now one of the great tropical gardens of the world. One of the inhabitants of this famous garden is "an indescribably lovely little frog, scarce a quarter of an inch long from stem to stern"; it had been described by Cope, and lost sight of for some sixty years. At Maracay, near Caracas, he saw the wonderful zoo which the old dictator Juan Vicente Gomez had formed, with the help of one of the Hagenbecks. Here enormous hippos lived in a pretty lake—around which giraffes, zebras and a host of antelopes wandered as if they were at home; and here were many greater rarities, such as spectacled bears from the Andes, the only bear in South America, and a whole colony of Pacaranas, or Dinomys, one of the largest of all the rodents, very curious and exceedingly rare, unknown to our own Zoo and to the British Museum.

Dr. Barbour is not less interesting when he talks freely of his fellow-men. He has some new stories to tell of Cope and Marsh, the two great palæontologists, bitter rivals and cunning foes; of David Fairchild, who married Alexander Graham Bell's daughter, and became a world-famous gardener and agriculturist; of Samuel Garman and H. F. Osborn and Leonard Stejneger; of E. S. Morse and of the much-loved "Uncle Bill Wheeler", who only died the other day; of President Lowell, and of Oliver Wendell Holmes (the judge not the professor) "who was one of the greatest men I ever knew—perhaps the greatest", but with one blind spot, common enough in frail humanity.

There is a modest paragraph about the luncheons in Dr. Barbour's own den in the Agassiz Museum—he calls it the "Eateria"—which Henry Bigelow and he set agoing years ago, and to which countless scientific men from all the world over have been hospitably bidden and been glad and proud to come. The cuisine is justly celebrated, even since "old Gilbert" died; and there are said to be tanks in the basement where turtle and terrapin await the illustrious guest.

This is a very human book, by a very lovable man. There is a certain oddity about it, and about him—which comes of working in a museum, and loving it, all his life long. For to be a true museum man, as Tom Barbour (or his daughter) says, "You don't *have* to be crazy, but it certainly helps".

D'ARCY W. THOMPSON.

## PSYCHOLOGY FOR MEDICAL STUDENTS

### Sane Psychology: a Biological Introduction to Psychology

By Prof. R. J. S. McDowall. A revised and enlarged edition of "A Biological Introduction to Psychology". Pp. xii+275. (London: John Murray, 1943.) 9*s*. net.

THE urgent necessity that the medical student should know as much as possible about the workings of the normal as well as the abnormal mind needs no underlining, though it has recently been emphasized by the General Medical Council. The present book, "for students of medicine, theology and education", is a brave attempt to meet these needs.

It seems fair to set down some requirements of a modern text-book of general psychology. (1) It should be simply written. (2) It should give numerous everyday examples of normal experience and behaviour, including that of children. (3) Abnormal psychology should not be regarded as determining the lines of normal psychology. (4) The concept of mental normality should be fully discussed, with especial reference to the relation of personality to culture-pattern; a normal commando-member who behaves like one, a week after the War ceases, will provide a headache for the ex-army psychiatrist also recently demobilized. (5) The theoretical and practical value to psychology of physiological knowledge should be realistically indicated; study in minute

detail of tiny bits of the lower animals is not always the best guide to a medical man trying to understand an intelligent delinquent or a hysterical amnesic. (6) It should appreciate the very extensive recent study of the individual personality, of idiographic as well as of nomothetic psychology. (7) The zoolatrous leanings of the early twentieth-century psychologists should be re-interpreted in the light of recent work by Americans. (8) And, arising out of (7), there should be recognition—especially desirable in a book written for 'medicals'—of the part played by culture in human life; by art, music, humour, philosophy, religion.

I suggest that Prof. McDowall be given good marks for (1), (2), (3), (5), and be referred for further study concerning (4), (6) and (8).

The medical student will welcome this book, with its convenient sub-headings, good index and bibliography. It will help him to answer examination questions, and provide excellent clinical examples when he is justifying psychological medicine to excessively extraverted athletes, or perhaps to his medically qualified father and grandfather. But another book, or lectures, will be needed to remind him of many happenings in the world of psychology during the last thirty years. One is the dropping of the word 'lunatic' and 'asylum' by the general public (writers on mental disease are catching up).

But many young students nowadays read psychology as part of their general education. They will rub their eyes at certain chapters in the present book and ask: Do nations think? Have nations instincts? What are the facts behind the assertion "the desire to learn may be largely hereditary" (there must have been a lot of hereditary learners lately in the U.S.S.R.)? Why is there nothing about the transformation and functional autonomy of human motives? Does the author's frequently and honestly expressed attitude towards medical practice and medical students merely reflect his own culture-pattern, and what would the recently qualified medical practitioner think of it?

A competent lecturer, however, can fill in these gaps—until, as I hope, Prof. McDowall does it himself in yet another edition of this book. But may we hope for a different title? Prof. McDowall is certainly a sane psychologist. Is there, however, such a subject as 'insane psychology'? Until I see books entitled "Schizophrenic Physics" or "Homophobic Biology" I shall continue to think the present title perfectly terrible. T. H. PEAR.

## VARNISH-MAKING

### Varnish Constituents

By Dr. H. W. Chatfield. Pp. xvi+496+12 plates. (London: Leonard Hill, Ltd., 1944.). 35s.

THE title of this book immediately carries the mind to varnish-making, a subject with its own small and select but most engaging literature for anyone who is willing to venture a little. Dr. Chatfield's book takes its place, as it were, at the end of the row; but how different it is from some of its predecessors. Naturally his book has been produced to the authorized war economy standard, but even without that measure of austerity, the book would still carry the air of battle-dress—business-like and efficient, everything set out in order, plenty of detail arranged in tabular form, a contents page (nine pages, in fact) minutely analysed, and a substantial index.

All this, no doubt, is in the spirit of the times, but how different from another notable book on the same subject by Sabin, written (actually it was re-written) and published during the War of 1914–18 and entitled "The Industrial and Artistic Technology of Paint and Varnish". Both these books have their place indeed, the one for the office and laboratory, the other for the laboratory and the leisurely student after business hours. It is to be hoped that the modern touch will not deprive us of the interesting historical references, the little anecdote, including, for example, the story of how the craft of varnish-making was brought to England and particularly to the city of Ripon, about 1770. Even the firm with which Dr. Chatfield is now associated has been engaged in the craft since 1803. Surely some historical survey of the subject, however short, is necessary to a full appreciation of the craft as it is practised to-day, for in spite of its strong chemical, and particularly synthetic chemical, background, it is still in large measure an art practised by craftsmen.

Working backwards in time, the present War has crowned the synthetic chemical aspect of varnish technology which grew between the Wars and became the outstanding feature of the period. To-day, many operations associated with varnish-making are carried on in a way sufficiently large to provide problems in chemical engineering; there will be more of them as chemical processing develops. Indeed, it is most likely that linseed oil, hitherto the oily bulwark of the industry, will come to be regarded more and more as a material for chemical manipulation into products which will in turn be regarded as the true raw materials of the industry.

The suggestion that drying oils from petroleum will be available after the War (for in the United States they are even now being used to some extent) is no idle boast, and the picture presented by the advertisements in current American technical journals, fantastic as they may appear to the older generation, do forecast more than a modicum of the shape of things to come.

The post-1914 war developments in varnish-making technology and the form they took were determined first by the widespread appreciation of the valuable properties of tung oil arising out of war experience with products made therefrom; secondly, there was the amazingly rapid development of the nitrocellulose lacquer industry, which is an almost classic example of turning swords into ploughshares.

The stirrings of mind and method which have brought the industry to where it is to-day began about the turn of the century or perhaps a little earlier. This was the time of the scientific revolution when organic chemistry began to open up, and when, to quote a few items that casually come to mind, rosin was esterified, Baekeland began his work on phenolic condensation products, and a survey was made of the natural resin resources of different parts of the world. The impact of this developing scientific background made manufacturers begin to think; but it was a long time before it was obvious to many of them (and indeed to-day it is not yet obvious to all of them) that it was necessary to abandon, or at least modify in favour of the scientific approach, those well-established methods which had flourished and served the industry so well during the period from about 1840 until 1900, when England was the premie

varnish-making country of the world and the industry enjoyed great prosperity. The eighteenth century was the period of transition. Up to then varnish was mainly associated with artists, and its making was part of their scheme of work. After then the uses of varnish became more widespread and various, and varnish-making gradually became a specialized industry. So one could travel backwards through the materials of medieval painting almost to the beginning of civilization and find much of interest relating to varnishes of one kind or another.

There is no doubt that this book will be appreciated, for even if Dr. Chatfield has not concerned himself with historical matters, he has collected a mass of useful and very up-to-date information about materials and their processing, which the worker in this field will find extremely useful. More and more of the products of chemical industry, particularly that part of the chemical industry associated with plastics, are being proved suitable as raw materials for varnish, in such variety as to force increased specialization and to develop a serious divergence in thought among technologists as to what is happening to the industry and what its future course will be. At the moment the varnish industry is certainly a case of chemical indigestion—much too much has been and is still being put upon the plate. Probably most of the technologists and scientific men concerned are trying to form, or maybe have formed, a working hypothesis to guide their actions; but it is doubtful whether many of them are wholly satisfied with their mental picture. This book will help to clarify some of the issues and may perhaps result in better co-ordination between the views of leading technologists. It will—and this is more important—help individuals who have only sketched in the barest outline of their mental picture of varnish-making in the post-war period.

In the author's preface, he says that, having felt the need personally for collected information about the properties of available raw materials and their manner of use, he has attempted to review the more important developments of recent years and to fit them into a complete whole. Unquestionably he has done what he set out to do and has done it extremely well. The review method he has adopted, however, has weaknesses, because so many references to patents and to other reported experimental procedures are inevitably included which are of no particular value and are sometimes misleading. In general, the reader is left to form his own judgment as to the value of the record given, but what is wanted is a weighted appreciation of all the evidence presented; indeed, in those sections of the work with which the author is clearly more at home he has done this to some extent in spite of his disclaimer that: "I have presumed to dogmatise and criticise as little as possible but rather to present the intelligent reader with the evidence from which his own conclusions may be drawn". The reader will surely form his own conclusions when he can, but he cannot always do so, and in any event he will like to have the professional's, that is the author's, conclusions as well.

As to the actual contents of the book, it is implied in what has already been said that the subject has been treated as on a broad canvas, with many items, some treated in fair detail, others less so, according to importance and the inclination of the author. There are no sections or aspects of varnish-making and varnish-making materials to which some reference will not be found.

L. A. JORDAN.

# RADIO WAVES AND THE IONOSPHERE

**Radio Waves and the Ionosphere**

By T. W. Bennington. Pp. vi+81. (London: Iliffe and Sons, Ltd., 1944.) 6*s*. net.

A VAST number of people are nowadays interested in one or other of the aspects of radio communication, and they are necessarily concerned with the manner in which radio waves are propagated around the earth's surface and to distances beyond the horizon. These and older students of the subject have become aware of the fact that such propagation is possible as a result of the existence of the ionosphere—those regions of the earth's atmosphere which become electrically conducting by ionization chiefly under the influence of ultra-violet radiation from the sun. It does not, however, require much delving into the subject to discover that the ionosphere is not simply equivalent to a metallic electrically conducting sheet in the same position at all times and seasons. It is rather in the nature of a series of partially conducting layers, one above the other, each varying in height and conductivity with time, and the lower layers sometimes shielding the upper ones from radio waves transmitted upwards from the earth's surface. Whether or no such upgoing waves are deflected back to earth from the ionosphere depends upon solar conditions, time of day, season of year, position on the earth's surface, and upon the frequency of the radio waves and the angle at which they are projected upwards from the earth.

While there is an extensive scientific literature giving the results of original investigations into this somewhat complicated subject, it has not hitherto been easy for the 'man-in-the-street' and the general scientific student to gain a clear view of the salient points in this field. In his recently published little book, details of which are given above, Mr. T. W. Bennington has filled this gap in an admirable manner; and he appears to have achieved his desire to provide a very lucid account of this subject for the benefit particularly of those whose knowledge is confined to school physics and the elements of radio communication.

The scope of the book is well defined on the comprehensive contents page, which has rendered an index unnecessary. After drawing a distinction between ground and sky waves, descriptions are given of the main properties of the ionosphere and the radio methods by which these are explored. The variations in heights of the various regions and their critical frequencies as determined by the density of ionization are described in some detail with the aid of well-selected samples of data obtained in Great Britain and in America. Later chapters deal with the part played by the ionosphere in long-distance radio transmission, and with the influence of the above variations and of ionosphere disturbances and other abnormalities on the effectiveness of the resulting communication. In addition to being written in an interesting manner, the book is scientifically accurate; and altogether the following comment given by Sir Edward Appleton in his foreword is well deserved: "Although it is primarily written for the professional radio technician who wishes to understand more about his own subject, I recommend it as a friendly and well-informed guide to anyone interested in long-distance radio communication."

# POST-WAR UNIVERSITY EDUCATION

By PROF. FRANK HORTON, F.R.S.

THE report of the British Association Committee on Post-War University Education, published on August 1, had its origin in the conference on Science and World Order held under the auspices of the Association in September 1941. The Committee was constituted under the chairmanship of Dr. Maxwell Garnett with the following terms of reference:

1. To consider the general policy and methods of university education with a view to promoting international collaboration and the free interchange of ideas, and relating university education to the needs and service of the community.

2. To consider the replanning of teaching departments and curricula in accordance with modern conceptions of the interrelation of different branches of knowledge, particularly those of science and the humanities.

3. To survey the position regarding teaching material, apparatus, books and staff in universities which have been damaged, disorganized or closed as a result of war, and to make recommendations for their rehabilitation.

The Committee published interim reports in 1942 and 1943, in which it set forth its views together with recommendations on various aspects of items 1 and 2 of its terms of reference, in so far as these deal with university education in the United Kingdom, particular points with which these interim reports have dealt being university entrance scholarships, university finance in Great Britain, universities and the public service and universities and adult education. The subject-matter of all these reports together with the findings of the Committee on other matters within its terms of reference are incorporated in the final report which is now published*. This has a preface by Sir Richard Gregory, president of the Association, and is divided into three sections corresponding to the items of the Committee's terms of reference, but deals in the main with those developments of general policy and methods which the Committee considers desirable in both school and university education in Great Britain.

How can we sum up what should be regarded as the outstanding educational needs of the community at the university-level, the satisfaction of which should be aimed at in university policy? The answer given in the present report is: (1) to get into our universities a larger proportion of those who are going to be the leaders of their generation; (2) having achieved this end, to educate them in such a way as to enable them to cultivate a wider and more integrated outlook on life as a whole; (3) for universities to take a far bigger part than they have done in the past in the education of those who enter the public service, not only before entry, but also after some experience of the service has been gained, and in providing an opportunity of university education for officials of lower rank than have normally enjoyed this privilege; (4) for the university schools of education to play an essential part in the education of all qualified teachers; (5) an expansion in the provision for vocational and non-vocational adult education.

The consideration of how to achieve the first two of these aims has led the British Association Committee to much serious criticism of present scholarship examination systems and of both school and university education. The Committee shares the prevalent view that a much more extensive provision of State and local aid to finance a much greater number of students through a university career is essential in our future educational policy. The Committee appears to envisage the increase of the number of these awards to such an extent that, after meeting the needs of all the candidates of outstanding intellectual promise, there would still be a number of awards available for candidates of less ability whose claims to consideration would be based mainly on their possession of social and civic qualities. It would seem that some adequate system would have to be devised for assessing the other factors which contribute to what the Committee terms "university-worthiness". The best the Committee can suggest in this respect is, after making awards to the candidates of high intellectual promise, "to pick the others empirically on a general impression of their scholarship-worthiness and without attempting an order of merit". Here we seem to be up against an identification of university-worthiness with scholarship-worthiness, and a disregard of the fact that, even if the number of awards is greatly increased, it is unlikely that this number will be as large as the number of candidates, so that an order of merit must be decided.

These awards are all spoken of as "scholarships" by the Committee, but we feel very strongly that the term "scholarship" should be limited to an award which is given for high intellectual ability and should not be applied to an emolument awarded mainly for social and civic qualities. The designation "State bursary" which has been used during the War to describe the emoluments awarded by the Board of Education, sometimes to students of little outstanding ability, might perhaps be continued.

It is suggested in the report that to prevent boys and girls of high intellectual ability from having to do a round of scholarship examinations in the hope of obtaining sufficient funds to finance their university careers, winners of open scholarships or exhibitions at Oxford or Cambridge (or successful candidates for admission to the women's colleges at those Universities) should be treated as if they had won national scholarships. So far as open scholarships are concerned it is generally agreed that this would be a good plan, provided the number of such awards is maintained at about its present level and the monetary value of the scholarships is not diminished; but it is clear that such a scheme, if adopted, must apply also to open scholarships awarded at other universities and not be limited to Oxford and Cambridge. In regard to the suggestion that all successful candidates for admission to the women's colleges at Oxford and Cambridge should also be treated in this way, one feels that the Committee cannot have realized the consequences of such action. The annual admission to the women's colleges at Cambridge is about 150 and at Oxford about 250, and thus the scheme might involve a yearly total of approximately 400 national awards being ear-marked for women at Oxford and Cambridge out of a grand total of about 1,600 annual awards contemplated for men and women together in all the Universities of England and Wales.

The outstanding theme which underlies all the Committee's criticisms of present higher school certificate examinations, university scholarship examinations and university curricula is over

* British Association for the Advancement of Science. Report of Committee on Post-War University Education. Pp. 52. (London: British Association, 1944.) 2s. 6d.

specialization, which the Committee, in common with other bodies which have published opinions on the subject, sees as a menace permeating the whole system of education and resulting in failure to cultivate a wide outlook on life as a whole. The universities are blamed for forcing this over-specialization on the schools by their system of selecting entrance scholars and also by supplying the schools with too high a proportion of specialist teachers. In its effect on boys who are not of exceptional intellectual quality, the scholarship system, especially that part which operates through the higher school certificate examinations, is described as giving rise to a product which, at the end of a university course, is scarcely adequate to the daily experiences and social contacts of a routine job in life. This condemnation of the whole range of the educational system is very sweeping, and we cannot but feel that the members of the British Association Committee must have been singularly unfortunate in their contacts with the products of that system who owe their university careers to their performances in higher school certificate examinations. The universities are taxed also with having failed to develop character and leadership, and with handicapping the growth of these qualities in that fraction from the poorer homes which is admitted to the universities through scholarships, by giving them a "one-sided education of a pernicious kind". So far as we can gather from the report, the perniciousness of the education lies in its specialized character and the lack of what the Committee describes as an integrating principle. 'Pernicious' is a strong word, and we do not see that any case is made out in the report which justifies its use.

The remedy suggested by the Committee begins with a new sixth-form curriculum in schools. The authors of the report would like to see a sixth form programme comprising "four general courses covering, respectively, the humanities, the social sciences, the physical sciences, and the biological sciences, affording a connected and complete, if not very profound, view of the whole of civilisation and life". It is suggested that English expression, a modern language, and sometimes mathematics might also be included, and it is envisaged that half the time spent in class would be devoted to these or a similar range of subjects, and the remaining half to the study of one special subject which would also occupy as much of the pupil's private study as he chose to devote to it. In recommending the allocation of so much of the time spent in class to non-specialist studies, the report goes beyond the suggestions in the report of any other body we have seen, and it is doubtful whether a pupil would gain any real advantage from the general courses unless he were encouraged to spend a proportionate amount of his private time on the subjects they comprise.

Alongside this modification of the sixth-form curriculum, the Committee recommends an increased encouragement of extra-curricular activities, and emphasizes that the effectiveness of the proposed changes would depend upon there being a corresponding modification of all scholarship examinations. It expresses itself as being strongly in favour of following this up by the introduction in universities of a type of general degree course, including both natural science and the humanities, which it hopes many students would take in preference to the more specialist courses. The report gives in some detail an account of what is envisaged as comprising such a course in "Philosophy, Natural and Social". One wonders whether those primarily interested in the study of the humanities would be satisfied with the share allotted to their subjects in the programme outlined. As a course for those chiefly interested in science, there is much to be said in favour of a syllabus of this kind, though there seems to be an over-estimation of what a student is capable of doing properly in a given time in the insistence that candidates for honours, in addition to being examined in the subjects of the course, should have also to translate and comment upon passages from French and German authors, *including set books*. If the study of the sciences outlined, their history and social significance, is to be serious and not the acquirement of a mere smattering of information, there would surely be little time available for any study of set books in foreign languages which would have real educational value.

For those undergraduates who choose to follow specialist courses in natural science, the Committee advocates the introduction of some study of sociology and citizenship by means of "special interest courses", general courses, and discussion groups, all conducted by persons understanding, and in sympathy with, the background interests of the students. It is not clear whether it is the intention that these studies should play any part in the examination for the degree.

In the conviction that it is the duty of universities to ensure that every undergraduate acquires some appreciation of the world as known by science, the Committee has set out what it considers should be aimed at in a course which is described as "Science for All". The list of subjects which is included in this course is very comprehensive and might perhaps be difficult to deal with in practice, but a strong case is made out for providing some such course.

Under the headings "Education for the Public Service", "Universities and the Education of Teachers" and "Universities and Adult Education" the report covers ground which has been explored by other committees which have recently published reports. The discussion on "World-wide University Collaboration" and the section on "Rehabilitation" gain special interest and importance from the assistance of distinguished academic members of the Allied Nations in their compilation.

In the section of the report which deals with university finance in Great Britain, we are glad to see the British Association putting forward suggestions which the universities themselves have been advocating for a long time, namely, an all-round improvement in the salaries of university teachers, the provision of residential accommodation for students of the newer universities on a much more extensive scale, an increase in the number of teaching officers and technicians on university staffs, and a much more generous expenditure than hitherto on facilities for research work.

On the question of salaries of members of university staffs the report emphasizes the present inadequacy of these in comparison with those ruling in other professions, and states that in the lower ranges they are, in some universities, insufficient to afford a reasonable standard of life under prevailing social conditions. The opinion is expressed that all whole-time professors in all English universities should be in receipt of "at least £1,500 a year at 1938 prices", and that certain subjects such as engineering and medicine should command salaries up to £2,500 per

annum, it being assumed that some form of family allowance scheme will be in operation and applicable to all university personnel. The report, however, makes no suggestion that the salary attached to the headship of a department should, in general, depend upon the size of the department or on the amount of administrative work attached to the headship, nor does it point out that a higher salary scale for all grades of staff should prevail in London, where living expenses are greater than in the provinces—a fact usually recognized in the salaries of other professional persons.

According to the University Grants Committee's "Returns from Universities and University Colleges" for the years immediately preceding the present War, the expenditure on staff salaries formed about one half the total expenditure of universities, so that a general increase in salaries on the scale envisaged will require a large total increase in university incomes. The present total expenditure on staff salaries is about £3¾ millions per annum, and it appears that the increase needed immediately to bring salaries up to the desired level is not less than £1½ millions per annum, a sum which is about two thirds of the present annual parliamentary grant to universities and university colleges in Great Britain. The Association's report points out that, for the future, universities will inevitably have to look more and more to local and national grants for the needed increases in their resources, and it urges that the Treasury grant should at once be doubled after the War. The rough estimate made above shows that a doubled Treasury grant would need to be supplemented by considerably increased grants from local authorities if university education is to be made available to a greatly increased number of students, for this would involve an enlargement of existing staffs and increased maintenance charges for libraries, laboratories, and social amenities. In addition to increased recurrent grants for maintenance, most universities are urgently in need of large capital grants for the purchase of building sites and for the erection of additional accommodation for students' residences as well as for laboratories, lecture rooms and other buildings.

A novel suggestion in the financial part of the report is that money received by a university for services rendered should not be included in its annual income and expenditure account, but should be paid into a capital account, so that the finances of the institution should not be embarrassed when the services cease to be rendered and the income from this source comes to an end. The earnings mentioned in the report are those of certain medical and scientific departments, but the proposal might perhaps be extended to cover the net profits (if any) from external and school examinations.

Universities are rightly zealous in safeguarding their autonomy, and, in some quarters, fears have been expressed that increased Treasury grants might involve some form of Government control. The British Association Committee states that "the question of control by the Government is certain to be raised", but is of the opinion "that the universities will be strong enough to resist any harmful requirements which the Government might be tempted to couple with substantial increases in State grants". While holding strongly that university autonomy must be preserved, we believe that it would be advantageous to university education generally if a definite lead were given in regard to the directions in which expansion of university activities is most desirable. In the last few months all universities have submitted to the University Grants Committee their schemes for post-war development, and it is hoped that, in due course, large sums will be forthcoming to finance these. It is perhaps unlikely that the total cost of all the developments contemplated will be provided from Government sources, and it seems desirable that when a university is allotted a grant it should be informed which, if any, of the items in its programme are considered to be unnecessary in the national interest, and which are the particular developments in respect of which support is given.

The duties in connexion with the work of advising the Treasury in the distribution of the Government grant to universities have been carried out for twenty-five years by the University Grants Committee in a manner generally recognized as being altogether admirable, and which has won the full confidence and gratitude of the universities themselves. It surely merits much higher commendation than the somewhat grudging praise given in the British Association Report: "We are of the opinion that the University Grants Committee has done very well in the inter-war years".

The report stresses the desirability of the creation of a universities' advisory council, which should include the vice-chancellors of universities and the principals of university colleges, university teachers of various grades and persons of distinction in other walks of life. The council would have the duties of formulating a national policy of university education and research, of advising the universities on all the national and international aspects of British university problems, and of making representations to the official body which advises the Government on the financial needs of the universities. It seems to us that a committee so constituted would be unwieldy in size, difficult to assemble and unlikely to be able to function usefully in the directions suggested. Moreover, it would be redundant in view of the existence of the Committee of Vice-Chancellors and Principals, and of the Universities Bureau of the British Empire, which latter body will doubtless be considering whether any extension of the range of its activities is desirable having regard to the conditions which will prevail after the cessation of hostilities. The University Grants Committee has recently been reconstituted and enlarged. It has always been able to command such additional expert advice as it has needed from any academic or Government source. It is in constant touch with the Committee of Vice-Chancellors and Principals, which already fulfils some of the functions set forth above. Moreover, individual universities are often in consultation with Government departments on matters of national and international importance, and it is right that this direct consultation should continue.

One wonders whether those who are pressing for the establishment of a universities' advisory council are really aware of the many claims which are made on the time of a vice-chancellor or of other persons who are specially qualified to speak on university matters. It is important to guard against the danger of such an increase in the time occupied by attending meetings that those who regularly fulfil their duties in this respect become automatically less qualified to offer advice, because of their enforced detachment from their primary duties in their universities.

# PROBLEMS OF MODERN PHYSICS*

By Prof. J. FRENKEL

THE War has shown up sharply the value of physics, and its achievements in the practical and in particular the military sphere. It is not in vain that from the moment the treacherous attack upon the U.S.S.R. began, the physics institutes of the U.S.S.R. (as of all combatant countries) were switched over, almost completely, to the solution of defence problems.

Although these problems are also basic problems of present-day physics, I shall not touch upon them at all here. My task is in brief to survey the 'normal' problems of modern physics, that is, those problems which physics sought to solve in peace-time, and to which it will return after the end of the War.

These problems can be divided into three groups:

(1) *Problems of theoretical physics.* These comprise, in the main, the explanation of phenomena which were discovered and studied experimentally some time ago. In a series of cases, however, theory has preceded experiment and predicted phenomena or laws which had been previously unknown. The most striking achievements of theoretical physics are among this type of prediction. It must be noted, however, that these predictions were in almost every case the outcome of a theory which aimed not at forecasting new, but at explaining old, phenomena. Outstanding theoretical workers have been able by this re-examination of old data to see in it features other than those which were thought to be known and understood.

A characteristic feature of any new theory, which does not try to fit new facts to an already established representation, but attempts a broader representation of the old as well as the new facts, is its irrationality from the point of view of previous ideas. This irrationality disappears only after these old ideas have been radically reconstructed. Striking examples of such 'revolutionary' theories in physics are Newton's theory of gravitation, Maxwell's electromagnetic theory of light (which predicted the existence of wireless waves), and the quantum theory of Planck, Einstein and Bohr.

(2) *Problems of experimental physics.* Here, as in the domain of theoretical physics, it is possible to distinguish two types, namely, the discovery of new things and phenomena (for example, X-rays, radioactivity, the neutron, the positron, etc.) and the detailed study of phenomena of which the general features only are already known. At first sight it would appear that we can discuss problems of the second kind only, because no one can know beforehand anything about phenomena which are still undiscovered. However, the conception of novelty allows a series of gradations, and if we have in view not only radically new phenomena, but also those which are in principle similar to ones observed previously, the search for such new phenomena can be included in a plan of scientific investigation.

(3) *Problems of technical physics.* Experimental physics is closely connected with theoretical physics on one hand and with technical physics on the other. In both cases this connexion has a two-sided character; that is, the respective parts of physics mutually condition and stimulate each other's development. In the realm of technical physics, we are concerned, generally speaking, with questions of utilizing the achievements of experimental physics for technical and, in particular, for industrial ends. In a number of cases, however, progress by technicians leads to the creation of new apparatus and methods of investigation, which open up new lines of development for experimental physics. Thus, for example, the development of radio-technics, which was the result of success in the study of electromagnetic and electronic phenomena, led in its turn to the creation of apparatus (electron counters, the electron microscope, the automatically operated Wilson chamber, the cyclotron) to which we are indebted for new knowledge in nuclear physics.

## Physics of Material Bodies

A discussion of the problems of modern physics could be based on the classification introduced above. It is more convenient, however, to make a division into two groups of a different kind: problems of a macroscopic character connected with the properties of material bodies; and problems of a microscopic character, dealing with elementary processes and elementary particles of matter, and the nature of matter itself. The tasks and methods of theoretical, experimental and technical physics can be rigidly separated into the two groups under consideration.

The physics of the nineteenth century studied successfully the external side of phenomena, which was directly accessible to experiment and observation. The physics of the twentieth century successfully concentrated its attention on the internal mechanism of these macroscopic phenomena, that is, on their microscopic essence. In this way it had succeeded by the beginning of the 'thirties in explaining all phenomena in terms of the movement and mutual interaction of unchangeable elementary particles of two kinds, electrons and protons, in agreement with the general principles of quantum mechanics on one hand, and of electrodynamics on the other. As a result, it was possible either to establish theoretically and verify experimentally or to establish experimentally and explain theoretically, the structure and properties of those ninety-two kinds of atoms from which all material bodies known to us are constructed.

By the structure of atoms I have in mind the number, arrangement and movement of electrons around their respective nuclei, which for the majority of physico-chemical questions can be treated as positively charged point particles. Within the framework of this scheme, the structure of the atom was studied experimentally and theoretically with as much thoroughness as, for example, the structure of our planetary system.

New problems are connected with the deep study of the structure and properties of the atomic nucleus, and also with the process of its transformation—the alchemists' dream of artificial 'transmutation of atoms', now accomplished although only under laboratory conditions. From the other side these new problems are connected with the more detailed study of the system which depicts atoms in their combinations one with another—as molecules, crystals and amorphous bodies.

The development of atomic physics in each of these two directions has a completely distinctive character. In studying molecules and material bodies, physics is dealing with phenomena which have been studied experimentally, and in part theoretically, for many

* Translated by E. R. Holmberg from *Vestnik Acad. Sci., U.S.S.R.*, 4–5 (1943), made available by courtesy of the Science Section of the Society for Cultural Relations with the U.S.S.R.

years, although from a more or less macroscopic and therefore inadequate point of view. The problems of modern physics in this domain consist principally of the theoretical explanation of accumulated facts, from a microscopic point of view, that is from the point of view of the modern picture of the structure of atoms and the behaviour of their constituent electrons and nuclei.

The application to these questions of quantum mechanics and electrodynamics had already led, if not to a quantitative then, in a large measure, to a qualitative explanation of the various phenomena. Modern physics has succeeded in laying the basis of quantum chemistry, and in determining the structure and properties not only of simple but also occasionally of complicated organic molecules and crystals. Here, in the majority of cases, physics has only confirmed or completed those ideas which were worked out earlier by chemists, at times just by feel, on the basis of indirect evidence.

It must not be thought, however, that all this progress was achieved in the realm of theoretical physics. X-rays and cathode rays (electrons) are powerful tools for experimental investigation into the structure of molecules and material bodies. But all the basic problems concerning the structure of systems more complicated than atoms, that is, consisting of several or many atoms, have a theoretical rather than an experimental character.

The modern theory of the structure of molecules and crystals is still very far from the stage of exactness which is achieved in the description of the structure of separate atoms. At the moment, there lies before physics the very wide (although perhaps not very profound) problem of the more quantitative development and clarification of our knowledge. Besides these structural problems, there lie beyond still further unsolved problems connected with the study of the processes which take place in molecules and material bodies under the influence of various factors, such as mechanical action, heat and cold, electric and magnetic fields, light, etc.

Problems of this kind by no means always need for their solution a detailed application of the ideas and methods of atomic investigation. In particular, this is true of problems concerned with the mechanical properties of solids and liquids (or more precisely of crystalline and amorphous bodies). Here can be observed a marked lagging of theory behind experiment and technical practice. It is sufficient to say that, until the present time, we have had no satisfactory theory of such well-known and practical phenomena as the friction of solid bodies; no quantitative theory of the plastic properties of crystals, that is, of their 'flow' under the action of sufficiently strong tension. Our ideas about the mechanical properties of solids and liquids have remained until the present time extremely simple and schematic.

Liquid bodies possess the properties of elasticity of volume, and viscosity under change of form. In recent times it has become apparent that liquids, besides having volume elasticity, also possess elasticity of form similar to a solid body; that is, besides plasticity, they possess rigidity, the latter being masked usually by the former. Further, a series of bodies has been studied which possess unusual properties, and which cannot be put into either of the traditional categories of liquids and solids. An example of these is resin, and other 'resinous' substances with a high elasticity which disappears at low temperatures, and also jelly-like liquids which have a wide application in the technics of to-day and possess completely individual elastic and plastic properties of structural origin.

The whole question of the 'unusual' mechanical properties of these substances, which are fortunately in most cases connected with their unusual electrical properties, is proof enough that a study of them from a theoretical as much as from an experimental point of view represents one of the tasks awaiting modern physics.

At temperatures near absolute zero, liquid helium occupies a certain peculiar position among these unusual substances. The striking experiments of Kapitza have shown that near the absolute zero of temperature helium completely loses the viscosity characteristic of normal liquids. As an explanation of Kapitza's experimental results, Landau has published an extremely interesting quantum treatment of the hydrodynamics of helium, based on the postulate that there exist two phases in liquid helium, a 'dead' non-viscous phase and a 'live' one possessing finite viscosity.

Landau's theory is in certain respects as unusual and 'irrational' as the experimental result it explains. But this is not sufficient to condemn it as a failure, because, as explained above, every new theory appears at first to be more or less irrational. However, the irrationality of a theory is not enough in itself to confirm its correctness. This can only be done by extending it to cover other phenomena, and then verifying its predictions experimentally (for example, in the case of liquid helium the proof of the theory is connected with the existence of two different velocities of sound in helium).

The absence of viscosity in liquid helium near the absolute zero of temperature is a mechanical analogue of the phenomenon of superconductivity, that is, the disappearance of electrical resistance, in a number of metallic bodies, at very low temperatures. Although this phenomenon has been known for some time, there is still to-day no satisfactory theoretical explanation of it, if we exclude certain attempted explanations of the fact that it occurs in two stages. The discovery of this explanation remains one of the real problems of modern physics, and in all probability it will need a basic alteration of our ideas concerning the normal conductivity of metals, along the lines of a more correct consideration of the mutual interaction between 'free' electrons, which condition this conductivity.

At the present time there is still great urgency about problems connected with the electrical, optical, photo-electric and thermo-electric properties of semi-conductors of electricity, in spite of the great progress achieved in this sphere in recent years, particularly by Soviet workers such as A. F. Joffe and his school. These substances occupy an intermediate position between metals and dielectrics, just as liquids are intermediate between solids and gas-like bodies. As a rule, they become more like insulators at low temperatures and like metals at high temperatures. The effect of temperature is to produce ionization; that is, it tears off the bound electrons, which can then move freely throughout the whole crystal and thus conduct an electric current. Radiation also serves as an ionizing agent, not only in the visible but also in the infra-red region. Under the influence of unequal illumination or heating, appreciable photo-electric and thermo-electromotive forces arise in semi-conductors.

At the present time, physics has to a large degree

learned how to manage the various properties of semiconductors principally by the method of adding to them a mixture of atoms which either easily give up their own electrons or quickly capture foreign ones. The development of this new domain of physics has already produced results of enormous industrial and technical value, although the future promises still more important technical applications. Perhaps it will be semiconductors which will help mankind to solve a basic technical problem in the not distant future when the deposits of accessible fuel coal and oil are exhausted. I have in mind the problem of utilizing directly the sun's energy by converting it into electrical energy by means of photo- or thermo-elements. The preliminary results obtained before the War by A. F. Joffe and his fellow-workers show that this idea is not Utopian, because the efficiency of rationally constructed photo- and thermo-elements is very high (this efficiency is appreciably greater in the case of semiconductors than in that of metals).

But from the purely scientific point of view, the study of semiconductors is still far from complete, and there are a number of very interesting problems connected with the subject which are as much theoretical as experimental. Among these must be mentioned that of 'localized' but free electrons in a crystal lattice, undistorted except for these electrons. Connected with this is the question of the motion of slow electrons and the existence of 'excitons,' that is, freely movable centres of electron excitation. This last question has particular importance for the understanding of the mechanism of certain photo-chemical processes in crystalline dielectrics. It acquires special interest in connexion with a new method of testing insulators electrically, which was put forward recently by B. I. Davidov. According to this method of testing gases, ionization takes place in stages, that is, the ionized atoms are first excited (just as in excitation, the ionization is caused by collisions of atoms with electrons which were freed as a result of a previous ionization). This hypothesis seems very plausible to me, although it cannot be accepted without further quantitative experimental verification. In particular, however much the gas test resembles the test for solid dielectrics, Davidov's hypothesis postulates the existence of free electrons (that is, excited atoms) in these solid dielectrics.

The intermediate role of semiconductors is analogous to that played in magnetism by the so-called meta-magnetic bodies such as magnetite and also a large number of chemical compounds of magnetic with non-magnetic elements. At moderate temperatures these bodies behave like ordinary ferromagnetics, but they lose their magnetic properties not only at high temperatures like ordinary ferromagnetics but also at low temperatures. This as yet little studied phenomenon of 'meta-magnetism' has probably an important practical application besides its great scientific interest. In particular, there is great practical value in the further study of the problem of obtaining ferro-magnetic, or rather meta-magnetic, alloys from non-magnetic elements. At the present time, only a few such alloys are known, and they possess very interesting magnetic properties. It is interesting to note in this connexion that there is an analogy with superconductivity. We now know of a series of superconductors (at low temperatures) which are alloys of elements not themselves superconductors.

The study of meta-magnetic phenomena requires the use of very low temperatures, although not so low as for the study of superconductivity, and the analogous problem of the disappearance of viscosity. These very low temperatures are also required for investigations into the optical properties of crystals, in particular for spectral analysis, and a large number of other properties of solid bodies which only become important in exceptional cases. Therefore one of the necessary subsidiary tasks of physics is to equip institutes with cryological laboratories and to improve further the methods of low-temperature work. (At the present time it is possible by magnetic methods to achieve temperatures of the order of one thousandth of a degree absolute.)

It must not be thought that interesting and little-known properties of solid bodies can only be demonstrated by means of super-low temperatures. In recent years there has accumulated a wealth of experimental material relating to transformations observed in crystalline bodies at medium and high temperatures. In contrast to ordinary allotropic or polymorphic transformations connected with changes in crystal structure and the emission or absorption of heat, 'transformations of the second kind' about which I am thinking only make themselves apparent by anomalous changes, over a fairly narrow interval, in specific heat, coefficient of expansion and a series of mechanical, electrical, magnetic and optical properties.

Similar transformations were first established by observations in the case of ferromagnetic bodies near the so-called Curie point, above which their ferromagnetism disappears. This is a phenomenon similar in character to the disappearance of superconductivity at low temperature, that is, the restoration of normal electrical conductivity, and to the transition of liquid helium from its anomalous modification II having no viscosity to the normal phase, helium I, with a finite viscosity.

Analogous transformations of the second kind were recently brought to light in certain metallic alloys. As was first shown by Bragg and Williamson, these transformations occur when the regularity of the relative positions of the different kinds of atoms breaks down. Thus, for example, in an alloy of zinc and copper in equal proportions, the atoms are arranged in a chessboard pattern at low temperatures, but at a transformation at a certain temperature analogous to the Curie temperature in ferromagnetics this alternating arrangement completely disappears.

Further, a series of crystalline substances is known, for example, compounds of halogens with hydrogen, methane and other paraffins, in which these second order transformations can be traced—wholly or in part—to disordering of the particles (or as Pauling thinks, in certain cases to the molecules changing over from oscillatory motion about regularly distributed equilibrium positions to free motion as in gases). These analogies do not, however, cover all the observed phenomena. Thus, for example, in the case of hydrogen chloride, one Curie point is observed which can be attributed to the molecules becoming disordered (or according to Pauling, to the transition to free motion); but in the case of hydrogen bromide, there are three such transformations.

Thus we can see that the experimental and theoretical study of second order transformations in crystalline bodies represents for modern physics a wide and as yet far from exhausted problem.

The formulation of a theory of the liquid state is a wide and urgent problem for theoretical physics.

Early attempts at a solution of this problem used the kinetic theory of gases and treated liquids as highly compressed gases. In more recent times the tendency has been to liken liquids more to solid bodies, lacking the greater orderliness in the arrangement of their particles, but still possessing that close packing which characterizes the crystalline type of structure. Since the liquid state is intermediate between the solid and gaseous states, it is natural to expect that the similarity between liquids and compressed gases becomes more or less exact at high temperatures (close to the critical temperature) and that at temperatures near crystallization liquids resemble solids. This kind of description, borrowing from the kinetic theory of gases on one hand and from the kinetic theory of crystals on the other, is, however, only an interpolation, having a limited value. There are sceptics who think that, in view of the great complexity of the problem, physics is only handicapping itself in explaining the structure and properties of liquids by such interpolations. Personally, I consider, however, that this scepticism is unjustified, and that further work towards perfecting the kinetic theory of liquids is one of the real tasks of physics in our time.

It must be mentioned that the performance of this task leads immediately to the necessity of radically altering our traditional ideas about the fluid state of bodies, first of all with the aim of removing the contradiction between the concept of plasticity and rigidity. As already explained above, the first of these does not exclude the second but only masks it. It is necessary, moreover, to bear in mind that the division of bodies, or rather aggregate states of substances, into solids and liquids does not accord with reality, which provides an extremely complex profusion of such states. Besides the liquid-crystalline (or mesomorphic) state which has already been studied thoroughly from the experimental side, modern physics knows of states which it is impossible to fit into the 'solid and liquid' scheme; for example, the resinous state, which as shown by very recent investigations can be encountered in such simple substances as sulphur and phosphorus. To phenomena such as these must be added the various jelly-like states which have hitherto scarcely been studied. But among those to whom the study of jelly-like systems (gels) presents enormous interest are the biologists, for recently physics has begun to penetrate into their sphere through the peculiar intermediate science of biophysics. So we see that one of the fundamental problems of modern physics is the experimental study of complex aggregate states and the construction of a molecular-kinetic theory for them.

The development of all natural sciences is closely bound up with the improvement of the apparatus with which natural phenomena are observed and which produces phenomena not encountered under natural conditions. In this respect physics differs from other sciences, for it creates new apparatus in connexion with new methods, not only for other sciences but also and in the first place for itself.

We have already mentioned above the remarkable phenomena of superconductivity and the disappearance of viscosity, which were discovered through working out methods of achieving very low temperatures. In this direction—the approach to absolute zero—physics has still, apparently, not reached finality; a number of properties of material bodies connected with the magnetic moments of nuclei need for their experimental observation and study still lower temperatures—of the order of one ten-thousandth part of a degree and lower. Physics has the means with which to do this (by using the magnetic moments of atoms and nuclei) but has still to use them fully. This is work for the near future.

In the region of high temperatures, modern physics has still not progressed very far. The maximum temperature achieved in the laboratory is somewhere around 20,000°, although as yet it has not been possible to observe the properties of any bodies at this temperature. In this respect more interesting results have been produced by astrophysics.

In recent times extremely important results have been obtained in high-pressure work. A few years ago, Bridgman succeeded in producing pressures up to 50,000 atmospheres, and further was able to study their effect on a series of properties of solids. More recently still, it has been possible to raise this limit to around 100,000 atmospheres, that is, approaching the order of pressures (about one million atmospheres) which prevail at the centre of the earth. One of the urgent tasks of experimental physics is to study further the properties of matter at these extreme pressures.

Besides these achievements in the realm of super-high pressures and super-low temperatures, physics has in recent years much increased the power of its observations by creating and applying the electron-microscope. Ordinary microscopes give a magnification not exceeding five to six thousand times. With the help of the electron-microscope it has been possible to increase this limit a thousand-fold, that is, to reach a linear magnification of the order of one million. The application of the electron-microscope has already produced a number of remarkable results in physics, metallography, colloidal chemistry and in particular in biology, for it has made possible the observation of individual 'molecules' of certain pathogenic viruses; apparently these molecules are able to grow and multiply, and represent forms intermediate between ordinary crystals and living organisms. The study of the new 'ultra-microscopic world' discovered by the electron-microscope will in the near future be one of the most important and fruitful tasks of so-called higher science. At every stage it brings forth new discoveries and sheds light on phenomena which were known before only incompletely. In this the electron-microscope will play as great a part as did the ordinary microscope in its time. A whole series of objects ranging from those of microscopic size of linear dimensions of the order $10^{-4}$ cm. down to particles not much larger than molecules now becomes accessible to direct observation and investigation. This is the domain which is of immediate interest for the sciences both of living and dead material.

Finally, there is still one more branch of physics which seems likely to make noteworthy progress. I am referring to the increases in frequency of artificially produced electrical and mechanical vibrations (ultra-short radio waves and ultra-sonic waves). Modern radio technics has succeeded in producing frequencies of the order of $10^9$ per second, which correspond to electromagnetic waves with a wave-length of less than 1 cm. However, between these radio waves and those of infra-red heat, there still remains the practically unexplored interval of wave-lengths ranging from some millimetres to a tenth part of a millimetre. But it is just this interval which is so interesting for the study of the electrical properties

of liquid and solid dielectrics (for example, absorption and dispersion should be very large). This interval of frequencies also presents great interest for the study of the mechanical properties of solids and more particularly liquids. This can be done by investigating the propagation through them of artificially produced ultra-sonic or hyper-sonic vibrations the frequency of which approaches that of their heat movements. The process of transforming electrical into mechanical vibrations has already been worked out; what remains is to increase further the frequency of radio-waves. During the last three or four years there has opened up a new way of attacking this interesting and important work by the use of klystrons and other electronic apparatus.

Summarizing, we see that the most interesting problems in physics are those connected either with limiting or with intermediate properties of material bodies. This conclusion holds also for other sciences besides physics, and further, the most topical problems are concerned not with those phenomena which are studied by definite specialized sciences, but with those borderline phenomena which fall between them. It is thus perfectly natural that these problems, besides being the most complicated, are also the least studied. A particular example of this is biophysics, the problems of which have been intensively studied by physicists for some time. In recent years, physics has attracted biologists to help in the solution of these biophysical problems, but physicists have not themselves shown much interest (if we except the physiological aspects of optics and acoustics). I am inclined to think that in the very near future this position must undergo a definite change, and that this part of the science front must conduct an extensive battle for new knowledge. I shall not attempt to enumerate the problems of biophysics because they are innumerable. Besides problems about the properties of gels mentioned above, there are those concerning photosynthesis, nervous and mental activity and electro-physiology (in particular, electrical vibrations in the brain). Finally, not the least interesting problem is that of the mechanics of living organisms (for example, the locomotion of animals and insects).

Not long ago, physical chemistry occupied the intermediate position which is now occupied by biophysics. At the present time, the formerly borderline phenomena have been completely assimilated into physics.

In its impetuous rush of growth, physics has of course been unable to prevent itself encroaching on the region long considered the province of chemistry. In distinction from chemistry, which is a science of materials and their transformations, physics, like sciences of other phenomena connected with matter, has lost this sense, by 'going behind' chemistry in discovering the structure of the chemical atom-elements and showing how to cause their artificial transmutation. In this way, chemistry has become a branch of physics, though it is true one of the largest, most interesting and practically the most important branch. In an exposition of the problems of modern physics, it would therefore be quite appropriate to include also the basic problems of chemistry. I shall, however, leave those problems which belong to chemistry in its narrow sense and pass on to those of the modern 'alchemy' which concern the atomic nucleus.

*(To be continued.)*

# OBITUARIES

## Dr. W. A. K. Christie

HIS numerous friends will receive with the greatest regret the news of the unexpected death of Dr. William Alexander Kynoch Christie, which took place in London on June 16, after a very short illness.

Christie was the youngest son of Charles Robert Christie and Margaret Catherine Paterson, both of Edinburgh, where he was born on October 2, 1882. He was educated at Daniel Stewart's College and Heriot's, Edinburgh, and then in succession at the Universities of Edinburgh and Zurich, where he took the degrees of B.Sc. "with special distinction in chemistry", and Ph.D. respectively.

After acting as Prof. Crum Brown's private assistant, Christie went to the Mond Nickel Co. in South Wales, until he was appointed to the staff of the Geological Survey of India to fill the newly created post of chemist to the Department. He took up his appointment in Calcutta on November 17, 1906. This he held until his retirement from the service on October 10, 1932, after a service of nearly twenty-six years, of which slightly more than five years was spent away from the Department. Of this, nearly two and a half years was during the War of 1914–18 in the Indian Army Reserve of Officers, from which Christie was drafted to the Special Reserve of the Royal Engineers in France, where his chemical knowledge was used in the service of his country.

With other officers of the Geological Survey who had gone to the War he was recalled in 1917, owing to the growing realization of the need of geologists and chemists to help in the production of war minerals. In April 1918 Dr. Christie's services were placed at the disposal of the Government of India in the Finance Department, whereon he was posted to His Majesty's Mint, Calcutta, as deputy assay master, later acting as assay master. He reverted to his post in the Geological Survey at the end of 1920.

In 1936, after a few years in retirement in England, Dr. Christie was again employed by the Government of India, this time as civilian technical officer in the Principal Supply Officer's Committee (India) under the Defence Department, India. He was in England on deputation at the outbreak of war in 1939 and was retained at the India Office, where he was still described as a civilian technical officer, a post he held until his death. In 1930 Christie married Miss Winifred Davidson, who survives him.

Christie's scientific activities were not confined to his official appointments, as is shown by the fact that he was a fellow of the Royal Institute of Chemistry, a member of the Institution of Mining and Metallurgy, a fellow and, in 1927, president of the Asiatic Society of Bengal.

Christie was one of those specially useful men of science who are qualified in two sciences, in his case chemistry and geology. While his chemical knowledge took priority and justified his various employments outside the Department, his wide knowledge of geology and mineralogy made him a valuable member of the Geological Survey of India, as he was often able to offer sound advice both to individual officers and to his director on problems involving both chemical and geological knowledge. With this scientific versatility Christie combined a proficient knowledge of French and German, both spoken and written, and an interest in the literature of both countries.

An additional facet of this versatility was Christie's

wide knowledge of, and sympathy for, his fellow men. Not only did these qualities cause him to give help unobtrusively to 'lame ducks' both inside and outside the department—no one ever asked his help in vain—but it also caused successive directors of the Survey to value his opinion on matters not strictly chemical or geological. They also made him a valued member of club committees (the Bengal United Services Club, Calcutta, of which he was at one time president, and the East India and Sports Club in London). Everyone who knew Christie will remember his ready wit and mastery of apt phrase. As an example one may recall that on one occasion the late H. S. Bion, very early in his service, telegraphed from the field that he had at last discovered calcareous algæ in the Lower Eocene of Burma. Christie suggested that the director should reply "The whole Department shares your ecstatic joy".

As chemist to the Geological Survey of India much of Christie's time was used on routine work and work for other officers; but on all occasions where ingenuity was needed he proved to be a prince of experimenters, the accuracy of whose work could be trusted to the last recorded decimal.

The total amount of work published from Christie's pen is small, but it is of the highest quality. His greatest achievement was the sampling of the winds of the Rajputana desert during the hottest season of the year, when shade temperatures up to 120° F. and more are registered. The then director of the Geological Survey, now Sir Thomas Holland, had instituted a detailed study of the salt reserves of Rajputana, particularly of Sambhar Lake. He had decided that a probable explanation of this large accumulation of saline materials was carriage by hot-weather winds from the salt-encrusted arm of the sea known as the Runn of Cutch. Christie volunteered to test this hypothesis and went to Pachbadra (intermediate between the Runn of Cutch and Sambhar), where he was aided by the late Rao Bahadur M. Vinayak Rao. All Christie's instrumental ability was brought into play, and, using methods that he had first worked out and apparatus that he had designed and tested in the laboratory in Calcutta, he sampled the wind at Pachbadra during April–July 1908. As a result he was able to show that during the hot weather of that year the amount of sodium chloride in the form of fine dry dust coming from the south-south-west that passed a front 300 km. broad and 100 m. high during the four hot-weather months might be indicated as 130,000 tons. This was in a year when the hot weather winds were unusually weak, so that this figure is probably well below the annual average influx of salt dust. The results of this study are discussed in a joint paper by Holland and Christie (*Rec. Geol. Surv. Ind.*, **38**, 154; 1909).

Christie also visited and discussed the soda lake of Lonar in Berar, and the well-known salt deposits of the Salt Range, in the latter case studying specially the potassic layers.

Another investigation of some interest was of a white efflorescence collected by me at the fissured surface of the Barari colliery, Jharia, then on fire underground. The mineral proved to be cryptohalite, a fluo-silicate of ammonium previously found only at a Vesuvian fumarole; its occurrence, with native sulphur, recalled the long-abandoned hypothesis that volcanoes owed their activity to the combustion of coal underground (*Rec. Geol. Surv. Ind.*, **59**, 16, 233; 1926).

L. L. FERMOR.

## Sir John Jarmay, K.B.E.

THE death of Sir John Gustav Jarmay on August 22 at the age of eighty-seven probably removes the last of those heroic figures who, with Ludwig Mond and John Brunner, struggled to found the ammonia soda industry in Great Britain and in the end established our greatest and most successful chemical industry. A Hungarian by birth, he studied at Zurich and came to England in 1875, working for a short time with Roscoe before he obtained a junior position with Greenall Whitley, the Warrington brewers. Ludwig Mond, who lived at first outside Widnes and later at Winnington, must have come across him and brought him in to help in 1877, four years after the start. It is a pity that no one has put these early days on record, days of continuous effort round the clock, of many failures and difficulties and always the courage of Ludwig and Frieda Mond to try again. Another helper was Carl Markel, tutor to Robert and Alfred Mond, a swarthy Stuttgarter of great originality. Jarmay made good and was chief technical manager when Brunner Mond was formed as a company: eight years later he joined the board of the company.

The expansion was rapid, but the technical progress was veiled in reticence and only through patents, many of which bore Jarmay's name, could the outside world glimpse what was happening. Close contact was kept with Solvays at Brussels, and there were developments in the United States and elsewhere, but the real hub of alkali progress was at Winnington. There Jarmay reigned and led a loyal and expanding team. When Ludwig Mond died in 1909, Jarmay took on added responsibility, and he continued to hold the reins firmly until the formation of Imperial Chemical Industries, Ltd.

Naturally he was one of the first consulted by Lord Moulton in 1915, and assumed responsibility for the production of nitrate of ammonia, T.N.T. and phenol. He achieved much and was recognized by the award of the K.B.E.: about the same time the war services of his wife earned her the D.B.E.

It is to Jarmay's credit that the need to establish nitrogen fixation plant in Great Britain was recognized as one which Brunner Mond were in honour bound to study, though it was a task outside their normal business and bound to be arduous and costly. The great works at Billingham and elsewhere to-day are a monument to his wise decision.

Jarmay was married in 1882 to Charlotte Elizabeth Wyman, a lady of great charm, who was of the utmost assistance to him: she made their house at Hartford Lodge the social centre of the staff. She died in 1938.

Jarmay the man looked an aristocrat to the fingertips. He hunted a good deal and was noted for his immaculate appearance in the hunting field—locally he was affectionately known as "The Squire". He spent his holidays abroad, being never more happy than when among the mountains and snowfields. On his retirement he lived in Italy until the outbreak of war.

E. F. ARMSTRONG.

## Mr. Henry W. J. Hathaway

HENRY WILLIAM JOHN HATHAWAY, who was killed accidentally on July 4, was born in London on October 27, 1915. He was educated at the Polytechnic School, Regent Street, London, and at the Imperial College of Science and Technology, South Kensington, where he read chemistry and geology, and took his B.Sc.

(Honours) in 1939, as a result of which he was granted his A.R.C.S.

Hathaway first held an appointment with Messrs. Murex Welding Co., Ltd., towards the end of 1939, working on the technology of tungsten. In January 1940 he joined the Fullers' Earth Union Ltd., Redhill, Surrey, as works chemist. Here he had full scope for his ingenuity in the development of chemical engineering processes. For many months he worked on an effluent treatment plant, assisting in its design, erection and eventual working, and carried out research into the utilization of the gel-like product. He worked hard to increase his theoretical knowledge of chemical engineering, and showed a remarkable flair for imbuing workmen with interest and enthusiasm. He could undertake almost any plant operation with his own hands, and was adept at making laboratory apparatus.

In July 1943 he joined Messrs. Bound Brook Bearings (G.B.), Ltd., Birmingham, where, as chief chemist, he supervised the installation and starting up of a new experimental laboratory. After a period as assistant to the works manager, helping on production problems, he began a comprehensive programme of experimental work on powdered metals. He took an active interest in the social side of works life.

Hathaway tried his hand at everything; he had a great thirst for experience. He was impatient with unnecessary delays and detested waste in factories or slackness in men. His creative urge, versatile hands and wide general knowledge would have carried him far, and industry has lost an unusually promising young life. He had been married only three months and is survived by his widow and his parents, of whom he was the only son.

ROBERT H. S. ROBERTSON.

WE regret to announce the following deaths:

Prof. Harry Berman, associate professor of mineralogy at Harvard University, on August 28, aged forty-two.

Mr. H. P. Marks, a member of the scientific staff of the National Institute for Medical Research for the past seventeen years, on September 13.

Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., during 1925–32 regius professor of physic in the University of Cambridge, on September 24, aged eighty-two.

Mr. W. H. Ross, O.B.E., formerly managing director and chairman of the Distillers Company, Ltd., and founder of the Ross Research Foundation for the Study and Prevention of Blindness, Edinburgh, on August 22, aged eighty-two.

# NEWS and VIEWS

## Mr. T. Raymont

MR. T. RAYMONT, the well-known educationist, celebrated his eightieth birthday on September 27. at his home in Carbis Bay, Cornwall. As an educationist, Mr. Raymont began his career in the chair of education in University College, Cardiff, in 1890, where he remained until 1905. He was then appointed vice-principal and later warden of Goldsmith's College (University of London), where he remained until 1927. There Mr. Raymont did some splendid work in the development of that College. During the difficult times of the War of 1914–18, he saved the College from extinction by his perseverance and common sense and above all by his absolute faith in its future. By his personal efforts he secured its survival and development in a greatly extended form as a training college for all branches of education. During that time, therefore, his reputation in the educational world became wholly established and his advice was keenly sought after. He was educational adviser to the National Froebel Union for eight years, besides being chairman for an even longer period. In 1928 he was president of the Training College Association and also of the Froebel Society. Perhaps Mr. Raymont's most well-known publication was "Principles of Education", which first appeared in 1904 and became a standard work that has passed through a large number of editions, the latest of which is still in demand. Other publications were "The Use of the Bible in Education", "Modern Education", and "The History of Education in Young Children". For many years Mr. Raymont has written in the educational journals. He has also been a regular contributor to *Nature*, and still is.

One of Mr. Raymont's daughters, who was formerly on the scientific staff of the Wellcome Historical Medical Museum, is the wife of Mr. H. J. Braunholtz, keeper of oriental antiquities and ethnography in the British Museum, and a past president of the Royal Anthropological Institute. Mr. Raymont's educational interests are shared also by Mrs. Raymont and two other daughters, all of whom have taught or are teaching in schools. We are glad to record that Mr. Raymont is enjoying excellent health, and still keeps in close touch with the general progress in education and science. The War has unfortunately interrupted his visits to London; but, in addition to his literary work, he finds a fruitful outlet for his energies in local educational affairs and in serving on the committee of the Penzance Library. We offer our congratulations to Mr. Raymont, and hope that for many years to come he will live to enjoy a very active life and continue to give educationists and men of science the benefit of his very wide knowledge and long experience.

## Chair of Zoology at Bristol

PROF. J. E. HARRIS, who succeeds Prof. C. M. Yonge in the chair of zoology at Bristol, has for some years been a University demonstrator in zoology at Cambridge. He is well known for his versatile contributions to experimental zoology, among which perhaps the most noteworthy is his analysis of the functions of the paired and unpaired fins of fishes. He has, however, also made highly original contributions to the physical properties of living cells, which may be expected to lead to results of widespread significance. Most of Prof. Harris's work has been carried out in Great Britain, but prior to the War he spent two years in the United States as a Commonwealth Fellow. For the past three years he has been in charge of a research unit under the Iron and Steel Institute. Prof. Harris may be expected to exploit to the full the admirable facilities which the Univer-

sity of Bristol has provided, in recent years, for the study of experimental zoology. The appointment of a man of Prof. Harris's wide interests and experience may be regarded not only as a source of satisfaction to the University of Bristol, but also as a good augury for the post-war development of zoology in Great Britain.

## Chinese Professors Visiting Britain

FIVE Chinese professors have just arrived in Britain, and will be guests of certain colleges at Oxford and Cambridge and of the British Council. They will continue their studies with the view of making British achievements in these fields better known in China. The visitors are: Prof. Chang Tsu-Kung, of the Central China University, an authority on the history of science, who is going to Christ's College, Cambridge; Prof. Yin Hung-Chang, of the Associated South-Western Universities (Tsing Hua), Kumming, who will do research in plant biochemistry, and will reside at St. John's College, Cambridge; Prof. Chang Hui-Wen, of the Central University of China, where he taught public administration and political science, who is to study public administration in Britain in connexion with the development of the Civil Service examination system in China, and will be attached to Corpus Christi College, Cambridge; Prof. Fan Tsen-Chung, head of the Foreign Languages Department, National Central University, Shapingpa, who will undertake research in English literature (with special reference to English knowledge of China), and will reside in Balliol College, Oxford; Prof. R. C. Fang, head of the Foreign Languages Department, Wuhan University, Kiating, who will undertake research in English literature, and will reside in Trinity College, Cambridge.

## French Scientific Mission in Great Britain

THE executive committee of the Society for Visiting Scientists received the members of the French Scientific Mission on September 16 at the Society's house at 5 Old Burlington Street, London, W.1. Prof. F. G. Donnan expressed a warm welcome to the Mission, which is led by M. L. Rapkine, and includes Prof. J. Hadamard, Prof. Pierre Auger, Prof. Francis Perrin and Dr. R. Wurmser. He said that French civilization and science are an essential part of those of Europe, and, as Voltaire might have said, if they did not exist, it would be necessary to invent them. He hoped that Anglo-French scientific relations will grow at a great pace and become one of the foundations of development in the post-war period. Sir Henry Dale supported Prof. Donnan, and looked forward with particular pleasure to the prospect in the near future of Prof. Hadamard being officially admitted as a foreign member of the Royal Society.

## Research in Cotton Growing

AT a meeting of the Administrative Council of the Empire Cotton Growing Corporation on June 6 several new appointments were made. Mr. Arthur Foster was elected chairman of the Council in succession to the late Sir Richard Jackson and Mr. James Littlewood vice-chairman. The post of director of the Corporation was filled by Mr. L. G. Killby, and Mr. J. C. May was elected secretary. Mr. Killby has also been appointed chairman of the Scientific Committee. The activities of this body have largely been concerned with the arrangements for establishing the new Central Cotton Research Station in Uganda. Though actual building operations cannot begin until after the War, a satisfactory site has been selected, and it is hoped that some preliminary work on it will soon be started. Mr. Parnell and Mr. Hutchinson have been designated for the posts of director and deputy director of the new Station respectively.

The Corporation's report for 1942–43, together with the programmes of work for 1943–44 of each of its seventeen experiment stations, has been submitted in the same form as in previous war years, and can be obtained, price 3*s*., from 37 Inner Park Road, Wimbledon Common, London, S.W.19. The research station in Trinidad is being closed in order that work may be concentrated in the larger cotton-growing countries with the new Station at Uganda as a central feature. This attention to development in research was commended by the President of the Board of Trade in his message to the Corporation at its annual general meeting for, as he said, efforts to improve the quality of cotton grown in the Empire and to increase its yield per acre is a valuable contribution to the prosperity of the Empire as a whole.

## Town and Country Planning

IN view of the important part which engineers are playing and must play in all future planning, the Council of the Institution of Civil Engineers has appointed an Institution Committee to be known as "The Town and Country Planning Committee" to advise the Council on matters relating to the engineer's part in town and country planning. This takes the place of a sub-committee of the Public Relations Committee, which had been dealing with this matter previously. The new Committee will include members who are city engineers and borough surveyors and others who have specialized on roads, railways, docks, water supply, drainage including sewage disposal, and electricity and gas services.

In order to enable engineers and others to keep in touch with present-day principles and ideas in planning, the Council has also arranged a series of four lectures on "The Position of the Engineer in Relation to Town and Regional Planning" on Thursdays at 5 p.m., beginning on October 26. Particulars of the lectures are as follows: October 26, "The Basis of Town and Country Planning", by Mr. H. J. B. Manzoni, city engineer and surveyor, Birmingham; November 2, "Traffic Problems", by Mr. W. S. Cameron, city engineer and surveyor, Leeds; November 9, "Drainage, including River Works", by Mr. D. G. Bevan, deputy city engineer and surveyor, Birmingham; November 16, "Services (Electricity, Water, Gas and Post Office)", by Mr. J. Paton Watson, city engineer and surveyor, Plymouth. These lectures will be open to non-members of the Institution on payment of 2*s*. 6*d*. for each lecture. Applications for tickets, accompanied by remittances, should be made to the Secretary of the Institution.

## Rickettsia Diseases

THE March issue of the *Boletín de la Oficina Sanitaria Panamericana* contains reports concerning Rocky Mountain spotted fever and the typhus group from five members of the Panamerican Sanitary Bureau Committee on Typhus, namely, Dr. Otávio de Magalhães of Brazil, Dr. L. Pãtino-Camago of Colombia, Dr. A. Recco of Cuba, Dr. C. G. Hidalgo of Ecuador and Dr. G. Varela of Mexico. There

were, in all, 791 cases of Rocky Mountain spotted fever and 9,625 cases of the typhus group. Brazil reported 663 cases of spotted fever in the fourteen years 1929–42, occurring in thirty-six localities of three States (Rio de Janeiro, Minas Gerais and São Paulo), but the report was admittedly incomplete and consisted only of the severe forms of the disease. In Columbia there were 128 cases of Rocky Mountain spotted fever during 1934–43 in seven localities in two departments. With regard to typhus fever (type not specified), except for Cuba where all the cases were of the murine type, Brazil reported four cases in 1941, Colombia 882 cases in 1942 and the first quarter of 1943 with a case fatality of 10–17·4 per cent in hospital cases. In Mexico there were 8,198 cases of typhus during 1938–42, with 750 in Mexico City, and a case mortality of 14 per cent. In Ecuador there were 517 cases of Rocky Mountain fever and 18 of typhus.

## Fulgence Raymond (1844–1910)

PROF. FULGENCE RAYMOND, a leading Paris neurologist, was born on September 29, 1844, at St. Christophe, Indre et Loire. He first studied veterinary medicine at the School at Alfort, where in 1867 he became director of the department of anatomy and physiology. Afterwards he took up medicine in the Paris faculty under Vulpian and Charcot and qualified in 1876. In 1894 he succeeded Charcot in his hospital practice and in the chair of nervous diseases at La Salpêtrière.

Raymond was well known in Great Britain, where he was made an honorary D.Sc. at Oxford and delivered a lecture at the Royal College of Physicians on "Premature Physiological Senescence localized to certain Organic Systems". He died on September 28, 1910. His chief publications were "Anatomie pathologique du système nerveux" (1886), "Maladies du système nerveux" (1889–94) and in collaboration with Janet "Leçons sur les maladies du système nerveux", "Neuroses et idées fixes" (1898), "Obsessions et la psychasthenic" (1903), "Etudes de pathologie nerveuse" (1910). He also made numerous contributions to the *Revue Neurologique* and *L'Encéphale.*

## Appointments in the University of London

DR. C. A. MACE, University reader in psychology at Bedford College, has been appointed as from October 1 to the University chair of psychology tenable at Birkbeck College.

Prof. W. H. McCrea, since 1936 professor of mathematics at Queen's University, Belfast, and since 1943 temporary principal experimental officer in the Admiralty, has been appointed as from October 1 to the University chair of mathematics tenable at Royal Holloway College.

Prof. Frank Goldby, since 1937 Elder professor of anatomy in the University of Adelaide, has accepted the appointment to the University chair of anatomy tenable at St. Mary's Hospital Medical School, and hopes to take up his post during the session 1945.

## Tapeworms in Seagulls and Cormorants

REFERRING to the report by J. B. Duguid and E. M. Sheppard of the infection of trout in a South Wales reservoir with plerocercoids of a tapeworm belonging to the Diphyllobothriidæ (see *Nature* of August 5, p. 185), M. D. Hickey and J. R. Harris (*British Med. J.*, 310, Sept. 2, 1944) report the finding of an adult tapeworm belonging to the genus Diphyllobothrium in seagulls and cormorants in the Dublin area. They think that these birds are the naturally infected definitive hosts of the parasite in this district. Trout from reservoirs near Dublin are heavily infected with plerocercoids belonging to the Diphyllobothriidæ. In the intestines of the greater and lesser black-backed gulls (*Larus marinus* and *L. fuscus*), of herring gulls (*Larus argentatus*) and of cormorants (*Phalacrocorax carbo*) the authors found all stages of the tapeworm from the plerocercoid found in the fish to the adult tapeworm. Investigation is proceeding and further details will be published later.

## The Night Sky in October

FULL moon occurs on Oct. 2d. 04h. 22m. U.T., and new moon on Oct. 17d. 05h. 35m. The following conjunctions with the moon take place: Oct. 8d. 16h., Saturn 0·3° N.; Oct. 14d. 01h., Jupiter 3° S.; Oct. 19d. 20h., Venus 5° S. The following occultations of stars brighter than magnitude 6 take place: Oct. 4d. 0h. 18·4m., $\xi^2$Ceti (*D*); Oct. 4d. 0h. 47·9m., $\xi^2$Ceti (*R*); Oct. 6d. 1h. 57·0m., 64 Tauri (*R*). The times refer to the latitude of Greenwich and *D* and *R* refer to disappearance and reappearance respectively. Mercury rises at 4h. 38m. at the beginning of the month and is in superior conjunction on Oct. 20. At the end of the month the planet sets very shortly after the sun. Venus sets at 18h. 22m. and 17h. 46m. at the beginning and end of the month respectively. Mars is too close to the sun for favourable observation. Jupiter, in the constellation of Leo, rises at 3h. 48m., 3h. 8m., and 2h. 22m., at the beginning, middle and end of the month respectively. Saturn, in the constellation of Gemini, sets at 14h. 09m., 13h. 16m., and 12h. 13m. at the beginning, middle and end of the month respectively. The Orionid meteors should be seen during October 18–26.

## Announcements

THE Committee of Privy Council for Medical Research has appointed Dr. Alan N. Drury (director of the Lister Institute of Preventive Medicine) and Prof. James C. Spence (professor of child health in the University of Durham and honorary physician to the Royal Victoria Infirmary, Newcastle-upon-Tyne) to be members of the Medical Research Council as from October 1.

THE Royal Aeronautical Society is arranging a discussion on civil aviation to be held on November 4 at the Institution of Mechanical Engineers. The discussion, which will begin at 10.30 a.m. and continue throughout the day, will be divided into sections dealing with economics, aircraft and aero engine design, route facilities (meteorology, radio, aerodromes, etc.) and the selection and training of personnel. The chair will be taken by Lord Brabazon. Tickets of admission will be available only through members of the Royal Aeronautical Society.

ERRATUM. In the communication "Standardization of Root Excretions . . ." by Dr. C. Ellenby in *Nature* of September 16, p. 363, for "a second sample is taken" read "the second oxygen determination is made".

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## The Magnetic Current

IN an article in *Nature* of February 5, 1944, entitled "Magnetic Current", Mr. James T. Kendall deals with movements of dia- or para-magnetic liquids in non-homogeneous magnetic fields, combined with electrodynamic rotations. He states that his horizontal magnetic field is not uniform (non-homogeneous) and observes the mass movement of the liquid as disclosed by refractive index striation without making use of the dark field of a microscope.

I am using vertical magnetic and electric fields of the highest homogeneity, separately and combined, so as to make those fields coincide with the gravitational field[1]. The two vertical cylindrical pole pieces, 6–12 mm. in diameter, have been adjusted so that their opposing circular faces are exactly horizontal and parallel, and the distance separating them can be regulated. In and around the space between these two pole faces (0·5–2 mm. apart) the movement of single microscopic particles in gases or particles and bubbles in liquids can be observed in the dark field of a microscope with low or high aperture. It is self-evident that observation with more sensitive means discloses new facts, permitting measurements of forces down to $8 \times 10^{-11}$ dynes. Those forces are measured by comparing them with the gravitational force exerted upon the single particle[2,12].

The essential facts proving the existence of the magnetic current are the following. (1) Polar movement of single particles to the north or to the south in a homogeneous magnetic field in gases, reversing their direction with the reversal of the field, their velocity depending on the field strength. The Peregrinus experiment of A.D. 1269 leads to a positive result when repeated with sensitive means. The above observation[3] leads to the concept of the magnetic ion, counterpart to the electric ion. Magnetic ions, north or south, can be produced by friction, by chemical means or by irradiation, as it is well known for electric ions. I have observed also magnetophoresis[4], the counterpart to electrophoresis (Reuss, 1809), as well as coagulation of matter in homogeneous magnetic fields.

(2) I have also observed magnetophotophoresis; it is the movement of particles of the same kind and size in and against the direction of the lines of force in the homogeneous magnetic field[5] when irradiated by concentrated light. They reverse with the field, their velocity being a function of the field strength and light intensity. This phenomenon is the counterpart to electrophotophoresis[6].

(3) I have observed magnetolysis of water, which is proved by the appearance of oxygen (up to 12 per cent per volume) if the two ends of one piece of soft Swedish iron immersed in acidulated water (1–4 per cent acid by volume was used) are magnetized north and south. In the blank experiment without magnetic field, pure hydrogen (0·00 per cent oxygen) is evolved[7]. The quantity of gas evolved depends on the field strength. A so-called permanent magnet of Alnico alloy, fitted with pole-pieces of soft Swedish iron, gave the same result, namely, oxygen was found in the gases evolved and more of the latter was found to be coming from the north pole than from the south. The north pole was attacked more strongly than the south pole and in every experiment a larger volume of gas was collected from the north than from the south pole. Chemical analysis of gas was not made in every case. These phenomena prove again that magnetism is polar[8].

(4) The permanent magnets used lost a portion of their pole strength during the magnetolytic processes as determined by search coil and ballistic galvanometer, and were found to be at a steady state before and after the tests. This is the counterpart of the loss in pole-strength of Volta's pile during electrolysis. The loss of pole-strength per second gives the average intensity of the magnetic current flowing between the pole-faces in absolute magnetostatic units. Using the standardization of the International Electrotechnical Commission, Brussels-Scheveningen*, 1936, the intensity of the magnetic current in practical units can be defined as follows:

Pragilbert $\times$ Intensity of Magnetic Current = Watt.

The magnetic currents measured in these practical units have had intensities up to $1 \cdot 7 \times 10^{-10}$.

(5) I have observed an electric vortex (whirl) around the iron wire connecting the two poles of an electromagnet or a so-called permanent magnet in a surrounding liquid bearing electrostatic charges. The same phenomenon occurs if the iron wire is covered by a thin electrically insulating material. This is the counterpart to the magnetic vortex (whirl) around the wire connecting the two poles of Volta's pile (using Oersted's own formulation). Using the dark field of the microscope, I have observed the circulation of a single electric charge, negative or positive, the direction of circulation being opposite in the two cases, this charge being on a bubble in liquid or on a solid particle in liquids or gases in or around the constant vertical homogeneous magnetic field. The intensity of the magnetic current measured electrically is equal to the work done by carrying a unit electric charge once about the entire magnetic current. This electric action of magnetic currents represents the third force in Nature besides the force of gravity and the well-known magnetic action of electric currents (Oersted, Biot-Savart, Lorentz). The use of this third force is *in principio* the magnetic motor[9].

(6) I have also observed that particles can carry simultaneously electric and magnetic charges; this has been concluded from the spiral tracks of bubbles and particles upwards and downwards in the constant vertical homogeneous magnetic field in gases and liquids. Their velocity of motion is of the order of magnitude of $10^{-2}$ cm./sec. in liquids and 1 cm./sec. in gases[10].

(7) It should be mentioned that there exists a polar movement in the geomagnetic field alone simultaneously with the north and south movements of microscopic particles of nickel or iron in gases at atmospheric pressure, when they are irradiated by light. They cease their movement when the magnetic field of the earth is compensated by an opposing field of the same strength and resume this movement if the compensating field is removed[11].

Furthermore, there is no ground for the doubt, raised by Mr. Kendall, about the validity of measurements of smaller charges than the electronic charge. I discovered and published this first in 1910 and finished this work in 1937, showing that on small

* For these data I am obliged to Brother Gabriel Kane, New York City.

spherical bodies of known density there are electrostatic charges smaller than the electronic charge. Using the same method, I found that the numerical value of the magnetic charge on a single particle, for example, of nickel in gas, can also be smaller than $4–5 \times 10^{-10}$ M.S.U.[12].

## Mechanisms for the Relaxation Theory of Viscosity

A RECENT communication by D. D. Eley and D. C. Pepper[1] describes experiments on the plastic flow of plasticized cellulose derivatives. They find that the flow velocity of compression of cylinders and extension of rods depends exponentially on stress at moderate stresses as the simple relaxation theory predicts[2,3], but at higher stresses flow velocity approaches linearity with stress. This behaviour at high stress leads them to question the applicability of the relaxation theory in general to flow problems.

We have observed this same phenomenon in the published data on other disperse systems, such as greases, paints and clay slips. In fact, the phenomenon appears to be characteristic of solid–liquid dispersions the flow of which has in the past been described by the Bingham yield-value equation.

The situation has been explained in the way which we now outline[4]. Consider a system where flow—or place exchange—involves the breaking of at least two types of bonds. Type 1 consists of strong bonds so that they flow according to a non-Newtonian law (at moderate stresses, the exponential law), while Type 2, being weak bonds, obeys the Newtonian law (that is, flow is proportional to stress). The total shear stress, $f$, is expressible as a sum

$$f = f_1 + f_2, \qquad (1)$$

where $f_1$ is the shear stress acting on Type 1 bonds and $f_2$ on Type 2 bonds. Now the rate of shear of each type of bond is given by the hyperbolic-sine law according to the relaxation theory. For the Type 1 (strong) bonds this general law simplifies to the exponential law

$$\frac{ds_1}{dt} = \frac{\lambda}{\lambda_1} k_r \, e^{f_1 \lambda_2 \lambda_3 \lambda / 2kT}, \qquad (2)$$

while for the Type 2 (weak) bonds the general law simplifies to the linear law

$$\frac{ds_2}{dt} = f_2/\eta_2 \qquad (3)$$

Here $\lambda_2\lambda_3$ is the cross-section of the flowing unit on which the shear stress acts; $\lambda_1$ is the distance between neighbouring moving units in the direction normal to shear; $\lambda$ is the distance jumped on each relaxation; $k_r$ is the frequency of the relaxation jump in the direction of flow, at zero stress, and has a well-known form according to the statistical theory of reactions; $\eta_2$ is the viscosity due to the Type 2 bonds, which can also be expressed in terms of the dimensions of the unit of flow and the frequency of the relaxation jump for the Type 2 process[2]; $k$ is the Boltzmann constant; $T$ is the absolute temperature.

Now the condition that the two types of bonds shall yield at the same rate is that the shear-rates be equal:

$$\frac{ds_1}{dt} = \frac{ds_2}{dt} = \frac{ds}{dt} \qquad (4)$$

The relation between total stress and shear-rate is thus

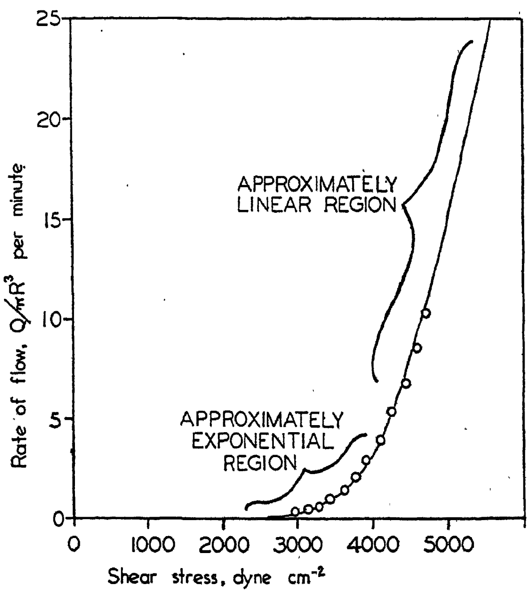
$$f = \eta_2 \frac{ds}{dt} + \frac{kT}{\lambda_2 \lambda_3 \lambda/2} \ln\left(\frac{\lambda_1}{\lambda k_r} \frac{ds}{dt}\right), \qquad (5)$$

which in its simplest form is

$$f = \eta_2 \frac{ds}{dt} + a \log \frac{ds}{dt} + b \qquad (6)$$

In agreement with the results of Eley and Pepper, Eq. (6) gives a shear-rate which depends exponentially on stress at small stresses where the term for breaking of Type 1 bonds predominates, and a shear-rate which depends linearly on the stress at large stresses where the term for breaking of Type 2 bonds predominates. The application of Eq. (6) is illustrated in the accompanying graph, where the equation has been fitted to the data of Blott and Samuel on a lime-base grease[5]. It may be mentioned that the above treatment gives a theoretical explanation not heretofore offered for the curvature always observed at low stresses in 'yield-value' plots.

Two additional tests of the correctness of the present interpretation are available. The first is



THE CIRCLES ARE EXPERIMENTAL DATA FOR A LIME-BASE GREASE STUDIED BY BLOTT AND SAMUEL. THE CONTINUOUS CURVE IS A THEORETICAL CURVE CALCULATED FROM EQUATION 6.

that the slope of the straight-line portion of the curve should correspond to a viscosity which is nearly equal to the viscosity of the Newtonian component of the dispersion. Goodeve and Whitfield have found this to be true for carbon black pastes[6]. The second test is that the temperature coefficient of the flow should indicate an activation energy in the low-stress region typical of the Type 1 bonds, while the activation energy in the high-stress region should have the much lower value typical of the Type 2 bonds. This is confirmed by the reported observations of Eley and Pepper, who find 30 kcal. and 11 kcal. respectively in the two regions.

Thus we conclude not that the relaxation theory of flow treated according to statistical mechanics is in question, but that, given the data on flow of a complex system, one can discover its mechanism.

RICHARD E. POWELL.

[6] Goodeve and Whitfield, *Trans. Far. Soc.*, **34**, 511 (1937).

Powell and Eyring have shown that the form of the flow/stress relation observed by us may be described by the addition of a second flow-process. Since this second process is postulated to involve weak bonds, it will be Newtonian on their theory.

We would note that the need to assume two types of bond is not so clear for a plasticized polymer as for a solid–liquid dispersion. In fact, Tobolsky and Eyring[1] have considered only one bond, of the strong type, in the flow of plastics, and have derived a theory of extrusion on this basis. Some point may be added to this objection by the observation that the test of Powell and Eyring, that the limiting viscosity of the system should nearly equal the viscosity of the Newtonian component (that is, plasticizer), fails when applied to our system. The former is $10^8$ poises, while the latter is 0·2 poises.

Powell and Eyring quote experiments on solid–liquid dispersions. It seems a somewhat lengthy extension of the theory of relaxation, to apply it to the forces between macroscopic solid particles. However, assuming this to be correct, their theory implies that as the stress is increased, the flow should first be exponential, then Newtonian, and *then once again exponential*, the last effect occurring when the stress $f_2$ on the weak bonds reaches values where $f_2\lambda_2\lambda_3 \gg 2kT$. This last effect has never been observed, but it would offer a possible test of their theory.

We would not claim that the above remarks definitely rule out some form of two-bond mechanism for our system, but we would submit that there is a case for examining all possible 'one-bond mechanisms'. The general notion of a potential barrier may be taken as essential to any theory of flow in plastics, but the specific features of Eyring's theory, such as the hyperbolic sine law for stress, have never been properly established. For example, a test of this law carried out by Tobolsky and Eyring on creep and stress relaxation in rubber and steel[2] was successful only up to a point, in that the viscous volume parameter, $\lambda_1 \lambda_2 \lambda_3$, was found to depend upon initial stress. The position cannot be clarified until a larger body of evidence is available on the flow of plastics and liquids, including especially Newtonian liquids, over the widest possible ranges of stress and temperature.

## Formation of Apatite from Superphosphate in the Soil

THE bulk of the phosphate added to soils as fertilizer remains in forms unavailable to plants. In calcareous soils it has been said to form hydroxyapatite. From a study of the reversion of mixtures of superphosphate and liming materials, MacIntire and his associates[1] have recently suggested that the ultimate form of some of the phosphate applied to heavily limed soils may be fluorapatite; but, so far as we have been able to ascertain, no direct evidence has ever been obtained of the actual presence in the soil of apatite formed from fertilizers.

The Broadbalk continuous wheat plots at Rothamsted provide favourable conditions for studying this question. Superphosphate has been applied to some of the plots annually for nearly a century, and the whole field had been heavily dressed with local chalk some decades before the experiments commenced. Since it appeared likely that the phosphate would accumulate in or around the soft porous chalk particles, these were isolated from samples of two plots taken in the spring of 1944. Such fragments (0·5–2 mm. diameter) from the plot (No. 5) with superphosphate but no nitrogenous fertilizer contained about 3 per cent $P_2O_5$, which is ten times as much as on the plot (No. 3) without fertilizer. On heating the chalk from plot 5 to 800° and extracting with carbon dioxide-free sucrose solution to remove calcium oxide, a residue was left which gave the X-ray powder diagram of apatite. A partial analysis of a 140 mgm. sample of the residue gave 47 per cent CaO, 26 per cent $P_2O_5$, 1·5 per cent F and 10 per cent insoluble in hydrochloric acid. (Some fluorine was lost during the ignition.) The refractive index was $n_D$ 1·601. Efforts to isolate the phosphate from the chalk without heating have not yet been successful, but X-ray diffraction data suggest that apatite is present.

Further analyses showed that where superphosphate had been applied, the phosphate content increased rapidly with decreasing grain size of the chalk fragments. The values for individual grains were highly variable, but consistent results were obtained by separating the whole of a given fraction from a bulk soil sample.

$P_2O_5$ PERCENTAGE OF CHALK FRAGMENTS FROM BROADBALK SURFACE SOIL (SECTION 4), 1944.

| | Plot 5 | Plot 3 |
|---|---|---|
| Mean values in whole fraction from 500 gm. soil | | |
| 0·5–2 mm. | 2·8 | 0·33 |
| 2–5 mm. | 2·0 | — |
| Individual grains 3–7 mm. | | |
| Mean | 1·4 | 0·13 |
| Extremes | 0·09–5·5 | 0·045–0·23 |

Analyses of chalk fragments from Plot 5 (0·5–2 mm. diameter, isolated from 100 gm. soil sampled in 1865 and from 500 gm. from later samples) showed that the phosphate and fluorine contents increased gradually with time, and at an increased rate from about 1888 onwards. From 1852 until 1888 the superphosphate had been made from bone ash, which contains little fluorine; afterwards mineral phosphate was used and considerable amounts of fluorine would therefore be added annually.

$P_2O_5$ AND F PERCENTAGES IN CHALK FRAGMENTS FROM BROADBALK SURFACE SOILS.

| | | % $P_2O_5$ | % F |
|---|---|---|---|
| Plot 5 | | | |
| | 1865 | 0·28 | n.d. |
| | 1881 | 0·44 | 0·032 |
| | 1893 | 0·80 | 0·045 |
| | 1901 | 1·15 | 0·078 |
| | 1914 | 1·7 | 0·11 |
| | 1944 (section 4) | 2·8 | 0.25 |
| Plot 3 | | | |
| | 1881 | 0·13 | 0·032 |
| | 1944 (section 4) | 0·33 | n.d. |

Throughout the experiment the plots have steadily lost calcium carbonate by leaching[2]. This may account in part for the increase in $P_2O_5$ percentage in the chalk fraction of the unmanured plot, but it can only be a secondary factor in the accumulation of phosphate in the chalk from Plot 5.

Further work is in progress on the formation of apatite in soils and its relation to phosphate fixation.

## Heredity, Development and Infection

DR. DARLINGTON'S[1] interesting article on "Heredity, Development and Infection" calls for two comments. He states that the "molecular system" of heredity, consisting of plasmagenes, "has been hitherto supposed to be purely maternal in inheritance". There is at least one case to the contrary in animal genetics. L'Héritier and Teissier[2] found that the character of susceptibility to carbon dioxide in *Drosophila melanogaster* was transmitted to all the progeny of a susceptible mother, but to a fraction only of those of a susceptible father. Kalmus[3] found that the same was true in an interspecific cross.

Dr. Darlington later cites Crane and Lawrence's[4] conclusion that roses may revert from the climber to the bush type as the result of bud-grafting on to a dwarf stock. He regards the agent transmitted as a plasmagene rather than a virus, since the bushy habit of growth in roses cannot be considered pathological. He later adds that "The high frequency of plasmagene and virus mutations, aggravated by the rapidity of their selection, both under nuclear control, gives an almost Lamarckian colour to their adaptation".

Lysenko and his colleagues in the U.S.S.R. have reported a large number of cases in which characters have been transmitted from one plant variety to another by grafting. They have been accused of Lamarckism, among other things. It would seem that British plant geneticists are now discovering similar phenomena. It may be that Lysenko, with the enthusiasm of a pioneer, has criticized Mendelian conceptions unjustifiably, as the biometric school did in Great Britain. But this is scarcely a sufficient reason for ignoring his work, particularly as some of his publications antedate that cited by Dr. Darlington. I yield to no one in my admiration of the work of the American drosophilists on nuclear genetics, which I supported in Great Britain when the chromosomal theory of inheritance was unfashionable. But perhaps we can also learn from our other allies.

## Pressor Effects of Amidine Derivatives

MANY compounds of general formula $R.X.C(:NH)NH_2$—where $R$ is an alkyl group attached to the amidine portion of the molecule either directly ('amidines') or through a divalent radical, $X$, which may be an oxygen atom (*iso*-ureas), a sulphur atom (*iso*-thioureas) or an imino-group (guanidines)—have in common a number of distinctive pharmacological properties[1-4]. Thus representative members of each series have been shown to raise the blood pressure of anæsthetized animals and to enhance the pressor effect of adrenaline by mechanisms which are either partly or wholly peripheral. The increase in tonus produced in different smooth muscle preparations is probably the result of a direct action on the muscle itself[2,3,4].

These investigations have since been extended. Preliminary tests were carried out with some two hundred compounds, the following effects, which were recorded as in previous studies, being looked for particularly as criteria of activity: elevation of the blood pressure in dogs and cats anæsthetized with sodium barbitone, increased pulmonary ventilation and an enhanced response to adrenaline. The evidence obtained strongly suggests that, whereas such activity is fairly widely distributed among amidine derivatives, it is inconspicuous, if present at all, in most related substances. Thus it was not apparent in imino-ethers or in ureas, thioureas, thiohydantoins, carbamates, thiocarbamates and similar compounds which have an amide or thioamide but not the structurally similar amidine group.

In the *iso*-thiourea series, where the relationship between structure and activity was studied especially, it was found that a variety of substituents could be introduced into the molecule without pressor activity necessarily being lost, salts of (2-methyl-)allyl *iso*-thiourea, (3-hydroxy-)*n*-propyl *iso*-thiourea, methoxymethyl *iso*-thiourea (I), (2-phenyl-)ethyl *iso*-thiourea, ethylene *iso*-thiourea (II), methyl N, N'-diphenyl *iso*-thiourea (III), and numerous similar derivatives all raising the blood pressure in doses of 1–10 mgm./kgm. Pressor activity was most evident in the lower homologues of methyl *iso*-thiourea but, unlike methylene di-*iso*-thiourea (IV), formamidine disulphide (V) had little effect on the blood pressure. A few related compounds (for example, hexamethylene

di-*iso*-thiourea) produced sustained falls. Derivatives with substituents in the amidine part of the molecule (for example, II and III) may cause well-defined pressor effects but, as a rule, activity is reduced or even abolished by this procedure. More examples of *iso*-thioureas displaying little activity were found in compounds like the hydrochlorides of acetyl and carbomethoxy *iso*-thioureas (which do not keep well *in vitro*) and *iso*-thiohydantoin (VI). Fewer amidine derivatives belonging to other series (guanidines, amidines, *iso*-ureas) were examined, but the results obtained indicate that the pressor activity of lower members is influenced by structural changes in much the same way as that of the corresponding *iso*-thioureas.

Many of the compounds altered the sensitivity of the preparation to the pressor action of adrenaline. The response to the latter was increased especially, but by no means invariably, by those pressor amidines which showed tachyphylaxis to a considerable extent. A decrease in sensitivity was also noticed sometimes, compounds such as carbomethoxy and benzyl *iso*-thiourea hydrochlorides often having adrenalytic effects in cats. These two salts, unlike most others, normally increased the pulse-rate.

Although the fifty-odd amidine derivatives which were shown to be pressor differ to a remarkable extent from the point of view of chemical constitution, they resemble one another more closely in the possession of certain physical properties. Measurements of the ionization constants of the parent bases show that the majority at least are strong electrolytes. The values obtained or found recorded for such *iso*-ureas and *iso*-thioureas ($pK_a \simeq 9$–$11$) are less than those for the corresponding amidines ($pK_a \simeq 12$) and guanidines ($pK_a \simeq 12$–$14$), but are still sufficiently high[5] to allow for 99–100 per cent ionization in water, if not in blood, at $p$H 7·3. No examples have been found as yet of weak amidine bases the salts of which are strongly pressor. On the other hand, some of the amidine derivatives which have little effect on the blood pressure were shown to be extensively hydrolysed in solution ($pK_a \simeq 7$ or less) and so should provide a smaller concentration of amidine cations than their more active relatives under the same conditions. Other strong organic bases (for example, ethylamine, tetramethylammonium, acetylcholine) may differ widely in their circulatory effects from typical amidine derivatives; possibly the basicity is of importance in so far as it determines access to the effectors[6]. In this connexion it is of interest that the pressor activity of amidine derivatives (but not apparently some of their other properties[7,8,9]) seems to be affected adversely by an increase in the length of sidechains even though the basic ionization constant may be unaltered or actually increased at the same time. The possibility that amidine cations alter the properties of cells through successful competition with inorganic cations of physiological importance has not been overlooked.

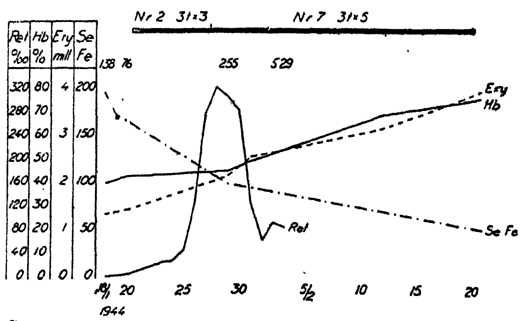
## Nature of the Anti-anæmic Factor (Castle)

IN a series of papers I have advanced the theory that the intrinsic factor of Castle might be identical with the enzyme aminopolypeptidase[1,2,3]. In brief, the experiments reported in these papers demonstrated that intravenous injections of crystalline secretin provoked in cats a secretion from the mucous membrane of the distal part of the pyloric and the proximal part of the duodenal region, the part of the alimentary canal from which the intrinsic factor is considered to be secreted[4,5]. The secretion contained a rather high concentration of aminopolypeptidase. In accordance with the results obtained by Castle, it was demonstrated that an enzymatic reaction (proteolysis) took place after incubating the secretion with a muscle extract. When preparing the enzyme from the hogs' pyloric mucosa, it was found that purified enzyme solutions apparently contained most of the intrinsic factor activity present in the mucous membrane. The intrinsic factor activity was estimated by allowing the purified enzyme solution to react with liver according to the methods outlined by Reimann[6] and Sjögren[7]. At this stage of the investigation (1941) the aminopolypeptidase had been purified about ten times. Since then, the enzyme has been further purified, in all about a hundred times.

The intrinsic factor activity of this purified enzyme has now been tested. The method of purifying will be published elsewhere. The estimation of the intrinsic factor activity of the purified aminopolypeptidase solution was based on the following experimental results. The concentration of aminopolypeptidase in the fresh pyloric mucosa was determined. Then it was easy to calculate the amount of enzyme activity present in the sample of pyloric mucosa used by Sjögren as intrinsic factor material. The next step was the determination of the aminopolypeptidase activity of vacuum-dried pyloric mucosa. This was the material from which the enzyme of the present investigation was prepared. It was found that half the original aminopolypeptidase activity was left after the desiccating process. As 1 gm. of the dried material corresponded to 6 gm. of fresh material, it was easy to calculate how much of the purified enzyme would be used in the activating experiment.

In the course of this, the aminopolypeptidase from 10 kgm. of vacuum-dried pyloric mucosa was purified a hundred times. As the yield by the method of preparation used was 25 per cent, the amount of aminopolypeptidase activity in the solution of the one hundred times purified enzyme was the same as in



GRAPH SHOWING RESPONSE IN A CASE OF PERNICIOUS ANÆMIA TO ORAL TREATMENT WITH LIVER PREPARATION Nos. 2 AND 1 ACTIVATED WITH ONE HUNDRED TIMES PURIFIED AMINOPOLYPEPTIDASE.

7·5 kgm. of fresh pyloric mucosa. The solution was halved (dry weight of each was 10·5 gm.). One half of the solution was substituted for the intrinsic factor activity of 3·7 kgm. of fresh pyloric mucosa in the activation of raw liver. This preparation was called No. 2. In preparation No. 1 the other half of the enzyme solution was substituted for the intrinsic factor activity of 7·5 kgm. of fresh pyloric mucosa. It was assumed that if the intrinsic factor activity had really been purified parallel with the aminopolypeptidase activity, then it should be possible to trace the activating effect of half the optimal dose of intrinsic factor on liver. The daily therapeutic dose of preparations 1 and 2 contained material from about 30 gm. of fresh activated liver, and were given orally to the patients in the form of 3 × 5 tablets. The preparations were tested with positive results on four patients with pernicious anæmia. The results of the treatment are demonstrated in the accompanying graph, which shows that both preparations, Nos. 1 and 2, are active. The clinical results, therefore, seem to favour the assumption that aminopolypeptidase may be identical with the instrinsic factor. A detailed report will be published elsewhere[8].

## Variation of Ascorbic Acid in Tomatoes

IN view of the wide differences of ascorbic acid content within various types of fruit and vegetables reported in the literature, we have recently carried out a study of some of the sources of variation in the tomato.

Our figures suggest that the sample size should be at least sixteen separate fruit taken at random from the batch or plot for any intervarietal differences to be significant, and this would indicate that many of the results quoted in the literature show divergences for this reason.

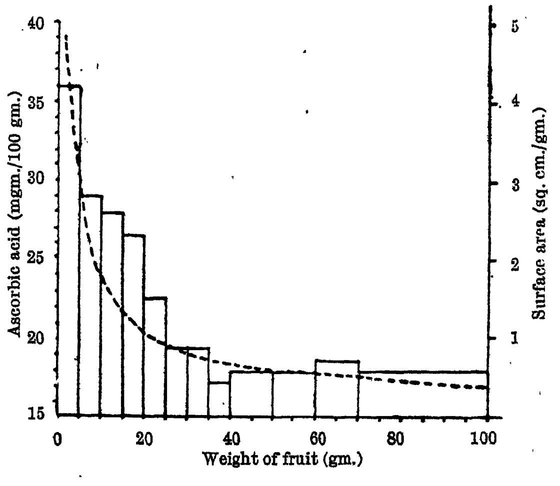
The fruits of any one variety may show wide variations, however.

We find that the ascorbic acid content of the fruits of one bush, although showing considerable constancy in all the fruit ripe at any one time, tends to increase as the plant ages. This was found to hold whether the fruits were collected from plants grown either during the spring when the days were lengthening, or during the autumn, when they were shortening.

We have also found a very marked bush-to-bush variation. The difference between the highest and lowest ascorbic acid contents found in the fruits of any one variety grown in one plot were of the order of 100 per cent (24–51 mgm./100 gm.). This is considerably greater than the variation between the mean ascorbic contents of the different varieties grown. By growing plants from the seed taken from tested tomato plants, we found that this plant-to-plant variation tends to persist in the crop of the following year. Selection in this manner seems to offer some prospect of building strains of any variety which would be high in ascorbic acid content and yet still possess desirable market qualities.

Most striking of all, however, has been the finding that the ascorbic acid content is closely related to the size of the fruit within certain size limits, as can be seen from the graph. The histogram of weight against ascorbic acid suggested that the tomatoes might be divided into two groups, separated at 30 gm. weight. Analysis of these figures showed that the fruit of less than 30 gm. weight gave a correlation coefficient of $-0·94$, highly significant at the 1 per cent level for the effect of weight on ascorbic acid. Those fruit of 30 gm. and more, on the other hand, gave a non-significant coefficient of $-0·03$.

All the fruit came from six bushes of one variety from which every fruit was collected and analysed. On the admittedly crude assumption that the fruit was spherical, the relationship between weight and surface area was worked out, and is represented by the accompanying curve. The close similarity between this curve and the histogram is obvious. As the weight increases there is a rapid decline in the surface area/weight ratio in the small fruit; but as the fruit becomes heavier, the decrease becomes less and less marked. If we make the assumption that the ascorbic acid is to a large extent synthesized in the fruit, by the effects of light rays, then the content of ascorbic acid present would vary with the amount of light energy received per unit weight of fruit. On this hypothesis, the wide surface area/weight ratio of the smaller tomatoes would be responsible for their higher ascorbic acid content, since for these the



ratio of light energy received to the weight of the fruit would be greatest.

The universality of this relationship even in tomatoes remains yet to be worked out, but these results at least cast some doubt on the value of the suggested use of *Lycopersicon pimpinellifolium*, which bears very small fruits, in a tomato breeding programme designed to produce fruits of a high ascorbic acid content[1].

Examination of other data available in the literature in the terms of this hypothesis may be fruitful. For example, a varying surface area/weight relationship may be partly responsible for the variation in ascorbic acid content of different species of Rosa previously attributed to genetical influences[2]. The increase in the ascorbic acid content in the tetraploid as compared with the diploid cabbage reported by Barr and Newcomer[3] is accompanied by a decline in weight. The same factors may be operating here.

The results will be published in detail elsewhere.

## The Laws of Nature

PROF. H. DINGLE's very interesting article[1] has laid bare in the clearest and most unambiguous terms the dubious validity, not so much of the distinction which the formulæ incidental to the historical development of science have imposed on our fundamental conceptions, resulting in an apparent deep-rooted contradiction between the equations representing the reaction of matter towards motion and temperature, but of an extension of the special theory of relativity which at present appears to pass without comment or challenge. It is usual to assume—and Einstein has himself lent authority to the assumption—that because the relativistic form of the equations of motion (apparently) for ever bar any measurement of absolute velocity relative to the framework of the universe, therefore absolute velocity with respect to any such framework does not exist; and, as a further extension, that it is trivial and useless to inquire what may be the quality of that framework, and whether or not there may be a luminiferous ether.

Prof. Dingle has shown that it is not difficult to conceive a relativistic statement of the laws governing temperature, relegating radiation to much the same position as the ether enjoys in the special theory of relativity. But if such a formulation were successfully accomplished, would we on that account be tempted to deny the existence of radiation? No, for we cannot escape its obvious effects. Let us now go one step further. Fifty years ago, an eminent school of thought attempted to replace atomistics by energetics; and had the work of the physicists which culminated in the discovery of radioactivity and the quantum been delayed another fifty years, science might well to-day have promulgated a dogma according to which it was trivial and useless to inquire whether atoms did or did not exist, and averring that their existence was after all improbable.

I do not for one moment wish to call into question the validity of the equations on which the special theory of relativity rests; their basis appears as reasonably assured as any of the fundamental bases on which science rests to-day, and all purely mechanical theories of the ether seem discredited. But it does appear somewhat incautious to assume that no subsequent developments will ever point to the probability of some spatio-temporal particularization of the framework of the universe and the existence of absolute motion with reference to it, even if the laws governing the measurement of all motion preclude us from measuring such absolute motion directly, leaving us only the possibility of inferring its existence from some otherwise inexplicable phenomenon. Lorentz's contracting electron is only one of a series of mechanisms whereby the impossibility of the measurement of absolute motion can be explained; and it appears invidious to argue about the philosophical probability or improbability of what is, after all, as yet only incompletely understood.

Incidentally, Prof. Dingle states that "a measurement of velocity in terms of the Doppler effect would have given us a finite limit in one direction and an infinite one in the other". This statement, while in no way invalidating the fundamental concepts on which the article is based (measurement in terms of the Doppler effect is primarily cited as a striking example of a measure of velocity invariant with respect to time), seems somewhat strange in an article of which the essence is a plea for "thermal relativity", inasmuch as the relativistic form of the Doppler equation gives an infinite limit for both approach and recession.

A. C. JESSUP.

"Chomlea", Claremont Road,
Pendleton, Salford, 6.

[1] *Nature*, **153**, 736, 758 (1944).

MR. JESSUP's letter raises what, I think, is a fundamental point concerning the significance of relativity theory. In adopting that theory, we do not assume that "no subsequent developments will ever point to the probability of some spatio-temporal particularization of the framework of the universe". We simply regard scientific theory as a description of the world apprehended by experience (more exactly, the correlation of experiences themselves), and require that it shall not include features for which experience offers no evidence. For that reason we regard a theory which includes the existence of absolute velocity as invalid. If future experience should enable us to detect absolute velocity, or even "leave us only the possibility of inferring its existence from some otherwise inexplicable phenomenon", the situation would be altered, and the same principle would then require us to include it in our description. In brief, scientific theory should be, so far as possible, conterminous with experience.

Mr. Jessup's statement that we cannot deny the existence of radiation because we cannot escape its obvious effects is somewhat ambiguous. We cannot escape certain phenomena, but the point is whether they are to be described as effects of radiation. If by radiation we mean something issuing from a body at temperature $\theta$, and proportional in magnitude to $\theta^4$ irrespective of the temperature of the surroundings (as is implied in the generally adopted theory of exchanges), then the above-mentioned principle requires us to deny it. All that we have been able to observe are effects depending on $a(\theta^4-\theta_0^4)$, where

$\theta_0$ is the temperature of the surroundings, and $a$ is a constant. The "obvious effects" are effects of *relative* radiation, just as obvious mechanical effects are effects of relative velocity. $\theta^4$ is (so far) unobservable *absolute* radiation, and is analogous to (so far) unobservable absolute velocity.

The relativistic form of the Doppler equation gives limiting velocities of $\pm c$. It must do this because it is made to conform with a definition of velocity (namely, $ds/dt$) which demands those limits. When I spoke of "a measurement of velocity in terms of the Doppler effect" I was imagining a *definition* of velocity measurement in terms of the relative change of wave-length. This would, of course, not lead to the ordinary relativistic equation, but to $d\lambda/\lambda = v/c$, where $c$ is a constant. Such a definition would, fundamentally, be as legitimate as the canonical one, and would enable us to describe the same phenomena, but the description would, of course, be different.

HERBERT DINGLE.

London, S.W.7.
Aug. 23.

## A Solar Halo Phenomenon

A PHENOMENON which I have not seen described before occurred in a part of the horizontal ring of a solar halo on August 9, 1944. It consisted of dark bands moving like waves through the very bright ring. The sky was very clear at Cambridge on the morning of that day when a cloud trail was formed by an aeroplane. The trail moved from north-west in an easterly direction. At 11.20 a.m. a section of the horizontal mock sun ring appeared in that part of the cloud which in the north-east had the same altitude as the sun. As the cloud moved on, being steadily deformed and taking the shape of the letter *S*, the halo shifted slowly from left to right.

About a minute later, I noticed dark bands crossing quickly through the brightness of the halo. They were of various grades of darkness and could not be seen continuously. Each band was about $\frac{1}{5}°$ in width and seemed to be perfectly straight. The distance between two adjacent bands was approximately $\frac{1}{2}$–1°. The middle one of a batch of bands was usually the darkest, the brightness of the brilliant mock sun ring being reduced by more than 75 per cent, while the accompanying bands were less dark. The best description of the phenomenon I can give is by comparing it with the rippling of the smooth surface of a lake by an occasional breeze. The bands moved from right to left and their speed seemed very high, approximately 5° per second, that is, very much faster than that of any cloud seen in the sky on that day. They gave the impression of being lower than the halo.

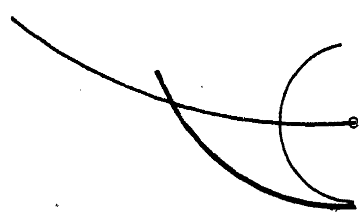
I called a second observer who independently noticed the phenomenon after I had directed his attention to the spot. A description was given in the words: "It is as if the ether waves have become visible".

At 11.25 a brilliant mock sun appeared on the right of the sun. The 22° halo developed and at 11.30 a mock sun could be seen on the left. However, no dark bands were visible in them. Later, a part of the horizontal ring appeared in another cloud trail at 11.45 a.m. The bright patch was this time in the north-west. First one dark band moved quickly through the patch in a northerly direction, taking about $\frac{1}{2}$ sec. to cross it. A few seconds later a whole batch of waves followed, going in a slightly different direction. Then lower clouds covered this part of the sky.

In attempting an explanation of the phenomenon three points will have to be kept in mind. First, the mock sun ring is a halo of the reflexion type produced by ice crystals the side faces of which are orientated in vertical planes and act as mirrors. A slight variation in the direction of the axes of the crystals has a marked effect on the appearance of the halo. I have seen fluctuations of brightness in another reflexion type halo before, namely, in the pillar above and below the sun, but the phenomenon described above is quite different. Secondly, the artificial cloud was less thick than a natural one. A high percentage of the ice crystals situated in the line of sight could therefore be affected simultaneously. Thirdly, different wind directions at various heights at the time of observation were revealed by clouds. Directions noted were north-west, north-east and south-west at ground-level. The deformation of the originally straight aeroplane trail to an *S*-shaped figure proves that the cloud was at a height where two different air currents came into contact. A disturbance may have been caused at the surface of contact, thereby affecting the orientation of the axes of the ice crystals. The swinging of the crystals about their position of equilibrium may have produced the observed optical effect.

G. H. ARCHENHOLD.
c/o Solar Physics Observatory,
Cambridge.

ON August 9, at 0900 G.M.T., numerous aeroplane vapour trails had spread out into wide belts of apparently cirrus cloud. Two mock suns were then visible, one at about 22° from the sun and one nearly opposite to it and at about the same height above the horizon as the sun. These mock suns disappeared after a few minutes.



At 10.30 G.M.T. portions of three halos appeared in the artificial cirrus. The first was probably the 22° halo, the second a concave arc of contact with it, and the third an arc of much greater radius which passed through the sun.

In the case of the two smaller halos the red colour was on the inside. The arc passing through the sun was colourless. The halos were very transient and I had no time to photograph them or to take angular measurements.

The accompanying diagram illustrates the approximate arrangement of the halos.

G. S. SANSOM.
Kennel Moor,
Milford,
Godalming,
Surrey.

THE communication from Mr. C. J. P. Cave[1] prompts me to record a somewhat similar experience. At 7.30 p.m. G.M.T. on the evening of August 3, the sky was clear except for a patch of striated cirrus cloud high up in the sky in a north-westerly direction. There suddenly appeared a band of colours right across this patch as if it were a rainbow. As the sun sank towards the horizon the band of colour moved downwards across the cloud, with an increase in the intensity of the colours. At one time part of a 'secondary' band of colour was visible, but this quickly faded as the band approached the lower edge of the cloud patch. The whole phenomenon lasted approximately fifteen minutes or so.

ERIC H. DOCK.

## Spectrum Formed on a Cloud

BETWEEN 8.55 and 9.00 p.m. British Summer Time on the evening of July 31, my family and I happened to be in our garden looking *towards* the setting sun. The sky was blue, broken by a few wisps of feathery cloud. When two wisps passed in turn at an elevation of roughly 60–70° between us and the sun, each showed a brilliant spectrum. The colours violet, blue, green, yellow, orange and red were clearly seen, violet being on top and red below.

The colours were much more brilliant than in any rainbow we have ever seen; they were evidently projected upon the clouds and the spectrum was therefore real and not virtual. There was no sign of rain at the time and the sun was a bright red ball, hidden from us by trees.

A spectrum such as above described may not be uncommon, but none of us has observed one before.

E. NIGHTINGALE.

58 Lemsford Road,
St. Albans.

## Smoke and Rain

IN a letter in *Nature* of August 12 (p. 213), Dr. J. R. Ashworth directs attention to the fact that the average rainfall at Rochdale on Sundays was 6 per cent below the average for weekdays during the thirty years 1898–1928, and that a similar deficit is evident if the data for the forty-five years 1898–1943 are used. It would have been interesting if he had quoted separately the figures for the latest fifteen years, 1929–43.

The average annual rainfall for each day of the week during 1929–43 can be deduced from the figures quoted in Dr. Ashworth's letter, and appear to be as follows:

| Sun. | Mon. | Tues. | Wed. | Thurs. | Fri. | Sat. |
|---|---|---|---|---|---|---|
| 5·69 | 5·56 | 5·54 | 6·37 | 5·90 | 6·21 | 6·42 in. |

The rather large variations between different days suggest that a period of fifteen years is too short to eliminate the effect of random fluctuations in the rainfall. Nevertheless, the fact that Sunday is only the third driest day suggests that the factors which previously caused Sunday to have the lowest rainfall have now ceased to operate.

Assuming that rainfall is increased by smoke in the atmosphere, the explanation is probably as follows: First, as Dr. Ashworth suggests, the increasing use of electric power has decreased the output of smoke from factories. Secondly, this has probably been accompanied by an increased number of private houses heated by coal fires, which are lit on Sundays as well as weekdays. It therefore seems likely that smoke from domestic coal fires is now a major factor in polluting the atmosphere of urban areas.

Carnforth, Lancs.

## Books: The Warehouse of Knowledge

I HAVE read with interest and appreciation your leading article "Books: The Warehouse of Knowledge" in *Nature* of September 9, 1944. That article is supported by "A Reading Survey" issued by the City of Leeds Public Libraries, and a corresponding survey in technical or scientific libraries might provide even more emphatic support. There are, however, two further points which I think should be borne in mind.

(1) Not only are books of importance for general education and technical training, but also the provision of adequate text-books and monographs on special subjects is of vital importance in research.

(2) Very few technical and scientific books of this class are now being published in Great Britain. The reasons for this are fairly clear from this leading article. The seriousness of this situation is not, however, sufficiently realized. Before the War any shortcomings in the British supply of books could be rectified by the supply of German and other European books as well as American books. The supply of such books has now been reduced to almost negligible proportions under the Trading with the Enemy Regulations, and it now appears that increasing difficulties are being experienced, owing to Government regulations, in obtaining from America the supplies of scientific and technical books which our research workers require for day-to-day purposes. The Government policy with regard to paper control is only part and parcel of a policy and attitude to technical and scientific books which tends to frustrate the effect of proposals for the expansion and development of research.

R. BRIGHTMAN.

Hexagon House, Blackley,
Manchester. Sept. 13.

## Importance of Film Records

REFERRING to Dr. M. Michaelis' communication in *Nature* of September 16, p. 365, I am, of course, well aware of the activities of the newly formed Scientific Film Association. Like the British Film Institute, however, it can only make contact with central organizations. These may or may not know what films are in existence on their particular subject.

Most scientific workers read *Nature*. It is to the individual maker of films that I appeal, in the hope that the learned societies may thus be persuaded to take action. Spreading the burden is preferable to allowing it to fall on the shoulders of any one organization, whose judgment as to what is and what is not worthy of preservation cannot be so authoritative as that of workers in the same field.

OLIVER BELL.

# RESEARCH ITEMS

## Columbia River Salmon

THE *Stanford Ichthyological Bulletin* (2, No. 6; Dec. 1943), published by the Natural History Museum of Stanford University, contains a paper by John C. Marr on "Age, Length, and Weight Studies of Three Species of Columbia River Salmon (*Onchorhynchus keta*, *O. gorbuscha* and *O. kisutch*)", being Contrib. No. 9, Department of Research, Fish Commission of Oregon. The salmon runs of the Columbia River have held an important place in the economic structure of Oregon and Washington since the beginning of their exploitation in the 1860's. The fishing intensity has increased constantly and the reduction of spawning areas, brought about by the construction of dams and other developments of water resources, have acted unfavourably to modify natural conditions and the productivity of the fisheries. In the genus Onchorhynchus the most important commercially is the chinook salmon *O. tschawytscha*; the next in importance are the steelhead *Salmo gairdneri*, the blueback *Onchorhynchus nerka*, the silver salmon *O. kisutch* and the chum *O. keta*, while the pink salmon *O. garbuscha* is not sufficiently numerous to be of commercial importance. As the runs of the chinook and blueback which ascend to the higher reaches of the river system are seriously depleted, the trend of the catch of silvers and chums has been upward in recent years due to an increased fishing intensity. Since they spawn in the lower tributaries they have suffered relatively less from the destruction of spawning beds. Thus they will probably become increasingly important in the commercial fishery, and their life-histories are now being thoroughly investigated. The present work deals in detail mainly with the age, length and weight of *Onchorhynchus keta* and *O. kisutch*. It is demonstrated that, in comparison with data from other localities, in both from south to north there is a decrease in mean length at the same age; older fish are progressively more abundant and the runs are progressively earlier.

## An Interesting Larval Trematode

R. M. Cable and Richard A. McLean record the occurrence of *Cercaria clausi* Monticelli, a marine larval trematode, on the west coast of Florida (*Notulæ Naturæ*, Academy of Natural Sciences of Philadelphia, No. 129; 1943). This is a rare type of cercaria which has the peculiar habit of forming rosettes, the tails clinging together and the bodies sticking out from the centre of the mass. The present specimens were found inhabiting the marine prosobranch gastropod *Lamellaria leucosphæra*, which in captivity gave out the cercariæ. There is an interesting point, namely, that the host of this worm is recorded as both *Lamellaria leucosphæra* and *Trivia europea*. Recent classification places *Lamellaria* and *Trivia* very close together and both possess pelagic larvæ of the echinospira type. It may very well be that the miracidium enters the host when in this pelagic echinospira phase. A search for such larvæ might be fruitful and of interest. If this supposition were proved, it would indicate a final host which was pelagic and not of necessity living always in the near neighbourhood of the mollusc. Photographs are given of the larvæ in this paper, but clear drawings are much needed also.

## Sporulation in Yeast

C. C. Lindegren and E. Hamilton (*Bot. Gaz.*, **105**, 316; 1944) and C. C. Lindegren and G. Lindegren (*Bot. Gaz.*, **105**, 305; 1944) have discussed the process of spore formation in yeast. After describing a new medium which gives the maximum spore formation of cultures, they show that the genetic constitution has a considerable influence upon spore formation. Legitimately diploid strains sporulate regularly and well, whereas single-spore cultures which may be either haploid or illegitimately diploid are irregular and sparse. The analysis of forty baker's yeasts showed that some were diploid while others were of single spore origin. Sporulation occurs more readily at the edge of the colonies where many of the cells are autolysed. These cells may supply necessary nutrients for the sporulation. It was known from the work of Nickerson and Thieman that riboflavin and sodium glutarate were specific substances for conjugation and sporulation. The parallelism with the paraphyses in Pyrenomycetes and with the structure of bacterial colonies is pointed out. From the cytological investigations of Lindegren and of Badian it would appear that chromosomes exist in bacteria and that they undergo similar changes to those observed in higher plants. There are two chromosomes in the diplophase of yeast. In a further paper by C. C. Lindegren and G. Lindegren (*Proc. U.S. Nat. Acad. Sci.*, **29**, 306; 1944) it is shown that the four spores of one ascus of certain strains of *Saccharomyces cerevisece*, which persistently produce haploid cultures from single spores, are of two types. Pairing and sporulation occur regularly and easily between but not within these two types. It is believed that allelomorphs controlling incompatibility are present as in fungi. The authors confirm the fact that *Torula* forms are imperfect forms of *Saccharomyces* and when properly mated produce copulation tubes of the pattern of *Zygosaccharomyces*.

## *Iso*-allelomorphism

C. Stern and E. W. Schaeffer (*Proc. U.S. Nat. Acad. Sci.*, **29**, 361; 1944) provide evidence for an important aspect in evolution. Three strains of *D. melanogaster* were homozygous and similar, except for the genes on the fourth chromosome which contains cubitus interruptus. At normal culturing temperatures 25–26°, these three strains all appeared to contain the similar normal allelomorph of *ci*. When raised at 14° one strain gives *ci* type individuals as well as normal. When this locus containing the normal allelomorph is present in flies deficient for the partner chromosome (hemizygotes) a different strain produces *ci* type individuals. When tested as heterozygotes with *ci* and especially with *ciw*, the normal allelomorphs of *ci* in the three strains are further separated. These *iso*-alleles have been found in many loci in Drosophila and in other organisms previously. The importance of the *ci* case is that the wild types in the three strains tested were found to be different. The prevalence of these small genic differences which have no immediate striking or switch effect is of great importance in evolution.

## Pathogenicity of *Ophiobolus graminis*

THE complex pathogenicity of the fungus *Ophiobolus graminis* on cereals is discussed in a brief paper by N. H. White and G. A. McIntyre (*J. Coun. Sci. and Ind. Res. Australia*, **16**, 2; May 1943). Eight single-spore isolates of the organism, derived from

eight ascospores within a single ascus, were grown upon three different media and inoculated on two kinds of sandy loam soil. All three of these factors affected the pathogenicity. One strain produced no disease; another infected 89 per cent of the plants. Relative differences between isolates were not the same for different media, though straw medium was generally most suitable and soil medium least so. Differences in pathogenicity due to variation in cropping soil were usually small, but changed with the isolates. Any control of this fungus must therefore overcome the extreme variability of the pathogen.

### Composite Nature of Spotted Wilt Virus

D. O. NORRIS announces in a short note (*J. Coun. Sci. and Ind. Res. Australia*, 16, 2; May 1943) that the spotted wilt virus of tomatoes is a mixture of at least three strains. The virus was obtained from potatoes at Canberra, and the three components form necrotic, ringspot and mild symptoms respectively. The necrotic strain appears to be identical with tomato tip blight described by Milbrath (1939) in Oregon. This discovery should explain the many observed variations in the severity of spotted wilt, for the symptoms will thus vary according to the number and ratio of strains which are present.

### The Sprengnether Vertical Seismograph

WILLIAM SPRENGNETHER, JUN., of St. Louis, has designed an instrument to meet the demand for a simple, low-priced, short-period vertical-component seismograph of fairly high sensitivity (*Trans. Amer. Geophys. Union*, 1941). The frame consists of a rigid truss with a long hinge-bar at right angles to it. Above the rear end of the truss a weight is carried by a vertical bar on which it is adjustable in order to regulate the period by setting the centre of gravity in any desired relationship to the point of suspension from the spiral spring. The principal part of the mass consists of this counterweight and of a brass box at the forward end of the truss containing a pair of elliptical brass spools on which are wound flat coils; and to a lesser extent of a copper plate supported on a forward extension of the boom or truss, adding to the inertia mass of the moving system. The hinge consists of two pairs of thin crossed springs attached to the hinge-bar of the moving system and to a rigid cross-piece fastened to the frame. The coil-box is free to move between the poles of a large, powerful Alnico magnet. The copper plate moves between the poles of three pairs of commercial Alnico horseshoe magnets, by which critical damping is easily obtained. Wires are led from the coil-box over the frame to the neighbourhood of the hinge-line and thence to a galvanometer. The period chosen in the case of one such instrument used at Saint Louis University lies between the microseisms, which usually have periods of 4–7 sec., and the local traffic disturbances, which have periods less than a second. The magnification is about 3,000. The instrument not only produces good records of local earthquakes, but it will also react to the shorter periods in the beginning of distant earthquakes to such an extent as to produce a sharp record of the beginning where horizontal seismographs of moderate high sensitivity will fail to do so.

### Experimental Measurement of Irrigation Water

A PAPER with the title "Medición de las aguas en las estaciones experimentales de riego", by Prof. Juan L. Raggio, with the collaboration of Juan C. Dragonetti and Adolfo E. Foglia, describes the method adopted for measuring with precision the volumes of water used for irrigation purposes at the experimental station attached to the Institute of Mechanics and Hydraulics at the University of Buenos Aires (*Rev. Fac. Agron. y Vet.*, 10, 111; 1943). An account of the gauges which were used is supplied, and the previous work of Prof. Giulio De Marchi is utilized. He showed how a simple calculation could determine the dimensions of the gauge ("Dispositivi per la misura di quota". *L'Energia Elettrica*, published in 1936–37), and continuing the work on his lines, a study has been made of the hydraulic processes developed in the gauge. A brief description of the irrigation system of the station follows, and a full account is given of the experiments carried out with the gauge to determine the coefficient of expense for various volumes. The paper is illustrated by a number of diagrams and by a chart showing the relation between the theoretical and actual volumes of water and also the coefficient of expense. On the basis of 5·5 litres of water per second, it is shown that the errors existing between the theoretical and actual figures do not exceed 4 per cent. A short appendix deals with the experimental plant on which the agricultural hydraulics of the Faculty of Agriculture of the University of Buenos Aires depends and in which the gauge was utilized.

### Differential Corrections to Double Star Orbits

W. P. HIRST has shown how an approximate arithmetical method can be used for applying differential corrections to the elements of the orbit of a double star (*Mon. Not. Roy. Astro. Soc.*, 103, 6; 1943). The usual procedure for deriving these differential corrections by the method of least squares was criticized some years ago by van den Bos, who pointed out that the result obtained is scarcely worth the work, and also that the elements that make the sum of the squares of the residuals a minimum are not necessarily the most probable (*U.O. Circ.*, 98; 1937). He described in the same issue a graphical method based on the residuals in position angle only. This method consists of plotting the residuals in angle as ordinates against any convenient abscissæ, such as the mean anomaly, or even the serial number of the measure, and comparing this graph in turn with the graphs of the differential coefficients of the equation of condition in angle, plotted against the same abscissæ. The residual curve is corrected differentially after each comparison to remove any systematic resemblance between the residual curve and the coefficient curve. The residual curve is then compared with the next coefficient curve and again corrected, and so on, until no further resemblance with a coefficient curve can be detected. Hirst's method is based on that of van den Bos, but it is much less laborious, and is applied to the orbit of A.417 (A.D.S. 16497). It starts with the function $\delta\theta/\delta e$, which is zero at periastron and apastron, positive from periastron to apastron in the direction of motion, and negative in the other half of its orbit. Hence, if the preliminary value assigned to $e$ is too small there will be, on the average, an excess of positive residuals in the half of the orbit after periastron as compared with those in the half preceding periastron. On this basis, it is shown that very satisfactory results are obtained with much less labour than is involved in the least square method.

# MEDICAL DEVELOPMENTS IN FIJI

A FULL report of the address given by Dr. V. W. T. McGusty, director of medical services, Fiji, to the Legislative Council on plans for the future of medicine in Fiji and its neighbouring island groups is given in the *Fiji Times and Herald* of February 24, 1944; and a leading article in the journal warmly commends these plans.

Dr. McGusty also gives in his address a very interesting history of medical progress in that part of the world. It is clear from what he says, from his discussions of his plans with the Colonial Office, from the approval of the plans by the Legislative Council, and from the discussions of the financial requirements of the reorganization proposed, that Fiji is going to incorporate in its medical services the medical developments which are now being organized in the Western world, and that it has both the ability and the personnel to make them as efficient as they are anywhere. The existing medical services are not to be thought of as being in any way primitive. The existing Central Medical School and the Nurses Training Centre and the Central Leper Hospital are joint services in which the New Zealand Government and the American administration of Samoa take part; and the Western Pacific Territories and the Australian Government are also concerned with some of them. All these services are discussed in Council Papers Nos. 2, 3 and 18*.

The difficulties of the medical man in these island groups, his Odysseys in conditions of bad weather and difficult landings in surf-boats, and the remarkably efficient help which the European or American practitioner gets from the keen and well-trained Fijian medical practitioners, are described by Dr. McGusty in this address and also in an article which he contributes to the *Native Medical Practitioner* (Vol. 3, No. 3; Sept. 1941), which is the journal of the Central Medical School, Suva. Other articles in this journal by native medical men and nurses show that Dr. McGusty's praise of them is well founded. There is an eagerness about their writing, and a desire to relieve suffering, which indicates a refreshing and noble realization of their mission. "I hope, sir," one of them writes in his report on seven weeks work on the island of Tongoa, "that you will enjoy reading this brief account of my first start in the New Hebrides." "Hoping," he concludes, "that all the students are working hard at their studies, and with best regards to you, sir, and all the students, your obedient N.M.P. and old student, A. K. Manulevu." What teacher would not be proud to receive such a letter and to do all he can to save such a race from extinction?

For it amounts to that—no less. "If serious infectious diseases," Dr. McGusty says, "such as malaria, can be kept out of Fiji, the Fijian race may survive." While tuberculosis is still the greatest single disease problem, the danger of the introduction of other diseases which can wipe out populations has always been a menace to Fijian medical care. The geographical position of Fiji renders it likely to become an important junction for civil air traffic after the War, so that its health problems will have more than a local interest. New Zealand is also extending its medical organization and desires closer co-operation with Fiji and the Western Pacific.

Fiji was discovered by Tasman in 1643 and, until the first Europeans arrived at the end of the eighteenth century, the infectious diseases of Western civilization were unknown to Fijians. After 1790, native folk-lore and other sources spoke of epidemics which took toll of a population of some 250,000, but this number had fallen fifty years later to 150,000. Protestant and Catholic missionaries probably introduced diseases, but they were, says Dr. McGusty, the only people who could control them or alleviate suffering, and full credit must be given to them for their work. The cotton boom brought more Europeans and more disease. The late King Cakobau, a very wise ruler, unified the country and led it into the care of Great Britain, to the colonizing power of which Dr. McGusty pays a warm tribute. The Fijian race was nearly wiped out in 1875 by an epidemic of measles which killed 40,000 people. The risk of the introduction of further infectious diseases was, however, vigorously combated by Sir William MacGregor, who instituted strict quarantine barriers, the vaccination of the people and the training of native youths to vaccinate and to practise medicine among their own people. This policy was carried on by Drs. Corney, Lynch and Montague.

The fight against infant mortality, which became serious enough to threaten the progress of the native races, was taken up in earnest, and further increase was checked by Miss Anderson's scheme for training Fijian girls as midwives and nurses. Miss M. L. Lea, principal matron of the Central Nursing School, tells us, in Council Paper No. 18, the history of this school and of its nursing services. Native methods of childbirth and artificial feeding are described in the *Native Medical Practitioner* (Vol. 3, No. 3; 1941), and from these accounts it appears that babies fed entirely on coco-nut prepared in various ways until they are more than eighteen months old may be as healthy as those that are breast-fed. Western methods are, however, rapidly effecting desirable improvements. Dr. McGusty, in his address, pays a high tribute to the work of the experts sent into these island groups by the Rockefeller Foundation, and in particular to the work of Dr. S. M. Lambert. Valuable also has been the opening to other island groups, by courtesy of the New Zealand Government and other authorities, of the Leper Hospital at Makongai. Half the deaths in this hospital in 1942 were Indians, a fact which may be considered together with the fact that the Indian population had, by 1942, risen to within 4,000 of the Fijian, and is expected to overtake and surpass it.

It is clear that the Government's plan to unify the medical services of all these island groups under the control of Fiji will do much to ensure the success of its scheme of improvement. The participation of New Zealand will be invited, and a director-general of public health and medical services for Fiji and the Western Pacific would be appointed, with a deputy director. The scheme includes the building, on a new site with adequate transport and facilities for expansion, of a new central hospital in Fiji of not less than 300 beds, an obstetric hospital of not less than 20 beds, a medical school for 80 medical students including 8 dental students, a nursing school for 150 students and a public health centre. The existing Suva Hospital, which is inadequate in size and equipment, could be altered to accommodate the

* Legislative Council, Fiji. Council Paper No. 18: Annual Report of the Medical Department for 1942. Pp. 24. Council Paper No. 2. Post War Reconstruction: Fiji and Western Pacific. Council Paper No. 3. Report on Public Health and Medical Services in the Colony of Fiji. (Suva: Government Printer, 1943–44.)

Public Health Centre and the administration of the Joint Pacific Public Health Authority and of the Medical Department of Fiji. In addition, it is proposed to use the buildings of the existing Colonial War Memorial Hospital, erected in 1923 to commemorate the fallen in the War of 1914–18, as a new and well-equipped isolation hospital. There will also be four regional hospitals, and the provincial hospitals will be improved. Modern research laboratories, built in 1936 with the help of the Rockefeller Foundation and of Lord Trent, are also available and adequate for present needs.

Of special general interest in view of the precautions which are being taken, all over the world, against the spread of disease in these days of fast transport and aerial travel, are Dr. McGusty's remarks about malaria. Malaria-carrying mosquitoes did not reach Fiji even in the days of sailing ships, although no special precautions were taken to prevent their entry. Dr. McGusty suggests that the south-east trade winds delayed the ships and washed their decks with salt spray, and also that their water-casks were always filled from fast-running streams in which mosquito larvæ did not develop. But the present War has brought an immense volume of traffic by sea and air, and it is a great tribute to the British and United States navy and army authorities that the precautions they have taken have so far kept malaria out of Fiji. How fatal to Fijians its entry might be, and how vital these precautions are, will be realized by those who have read the note in *Nature* of May 20, 1944, p. 625, on the importance of all human parasites in times of war, and on the very serious results which may follow their attack on populations which are not accustomed to them.

Council Paper No. 3, which is a report on the public health and medical services of Fiji made by Dr. Watt, director general of health, New Zealand, and Miss Lambie, director of nursing, New Zealand (the Watt-Lambie Report), illustrates the co-operation between Fiji and New Zealand which the Legislative Council of Fiji wishes to encourage. This report is not merely a report on the health of Fiji; it is also a valuable essay in modern public health practice. Plague and smallpox are, it points out, constant menaces to countries in the Pacific. They can be combated by the quarantine system and measures for rat control recommended by the report and by vaccination for smallpox. The importance of keeping out anopheline mosquitoes is emphasized. The other quarantinable Fijian diseases are yellow fever, cholera and typhus. The recent discovery of the efficacy of *DDT* as a means of killing the lice which transmit typhus and its successful application to large numbers of people in Naples recently should greatly assist the control of this disease in Fiji as well as elsewhere in the world, if, indeed, it does not check its ravages completely. The principal infectious diseases in Fiji are tuberculosis, typhoid fever, dysentery, diphtheria (which is not a major problem) and yaws and hook-worm (which are being well handled).

Tuberculosis is a serious problem in all native races and this report recommends mass miniature radiography, as well as the other measures usually used for its control. Local housing standards are usually good, but it is feared that tuberculosis may increase as the number of town dwellers increases. The pasteurization of milk in the larger communities, or in some places the boiling of it, are recommended, and this should help in the control of tuberculosis as well as that of typhoid and some other illnesses. The control of typhoid and dysentery depends upon safe milk, water and food and on efficient sanitation and general cleanliness. Better supervision of meat supplies and of milk production and improvement of housing, drainage and sewage disposal are required in some areas. The report discusses in some detail the organization and staff of the medical department, the maternal and child-welfare services and the existing hospital services (reports on the last-named constitute an appendix to the report). Other sections of the report deal with the medical, dental and nursing services and with medical and health education. The criticisms of these are, in the main, met by the scheme of reorganization outlined above.

The authors of the report think that Fiji will become a natural centre for medical research and education for the various island groups of the South Pacific. Its excellent climate and freedom from malaria and other tropical diseases should help this development.

Everyone will wish success to the medical authorities of Fiji in the carrying out of this beneficent scheme. The peoples of these island groups deserve all that we can do for them when, before very long, their sunny land will be freed from the shadow which has recently menaced their future. G. LAPAGE.

# FEDERAL ACTIVITY IN AMERICAN EDUCATION

IT is not easy, for a non-American, to understand why each of the forty-eight States of America should be educationally autonomous, and why therefore it is difficult for anyone to speak for American education as a whole. This is but one aspect of the opposition between Federal Government and State rights—a matter incomprehensible to a person who is unacquainted with the broad lines of American history and has never travelled in the United States. But war is a national effort, and must be conducted by the nation, in this case with powerful collateral effects upon the forty-eight educational systems. Thus the United States Office of Education at Washington, headed by the U.S. Commissioner of Education, is extremely active, and by the use of the funds provided by the Federal Government for educational purposes is able to promote the ends of a nation at war. So much is made clear by the Annual Reports of the U.S. Office of Education 1941–2 and 1942–3, by the pamphlet entitled "Federal Government Funds for Education 1940–1 and 1941–2", and by the official bi-weekly journal *Education for Victory*, which replaces *School Life* for the duration of the War, and which is specially addressed to all American youth.

Among the war-time causes aided by the U.S. Office of Education agriculture takes a very prominent place, followed by vocational education, vocational rehabilitation, national defence training, library service, adjustment of college curricula to meet war-time needs, teacher personnel problems, not to speak of a long list of less important subjects.

Another way in which the U.S. Office of Education conveniently speaks for America as a nation is exemplified by pamphlets entitled "Inter-American Education: A Curriculum Guide", and "Education in Cuba". The former represents a concerted effort on the part of the U.S. Office of Education to establish a plan for making the study of the other American

republics an integral part of the curriculum in primary and secondary schools. The latter is one of several basic studies on education in the other American republics planned as a part of a programme to promote better understanding of education in the Latin-American countries and to encourage closer educational co-operation.

The U.S. Office of Education does not limit its educational surveys to the American continent, but extends them to the wider field of what is known as comparative education. A good example is Leaflet No. 69, which provides a clear and interesting report on "Education in China To-day". The report shows how, despite the invasion of her best developed educational centres, China is to-day demonstrating an unshakable confidence in public education. It seems quite obvious that the Central Office of Education in the United States is doing most valuable work which does not fall within the purview of any one of the forty-eight States.

## RESTORATION OF THE LENINGRAD INSTITUTE FOR PLANT CULTURE

By IVAN BONDARENKO*

BEFORE the War, the Leningrad Institute for Plant Culture had formed a valuable collection of seeds of many species of plants. When the siege of the city began, most of the scientific workers were evacuated into the interior of the U.S.S.R., but the seed collection had to be left behind at Leningrad. As soon as the city was freed, the workers returned.

Johann Eichfeld, who came back with a number of assistants, began re-sorting the collection; in the early spring he sent about ten thousand samples of various seeds to different parts of the Soviet Union with the request that they should be planted and a report on the growth furnished to the Institute. Telegrams have already been received reporting results from the Urals, North Caucasus, the Moscow region and Central Asia; in nearly all cases the results have been normal. This shows that, in the main, the collection has not been disturbed, and that with its help new research can be undertaken and the task of helping the restoration of regions devastated by the Germans can be tackled.

The Institute workers are now busy rebuilding their experimental station, which is situated three miles from Pavlovsk near Leningrad. This was formerly a big experimental farm where there were about two hundred varieties of fruits, three thousand varieties of berry fruits (including the only collection of gooseberries in the U.S.S.R.), about fifty thousand hybrid fruit trees and bushes, and many flowers and decorative plants. The station had cherries which ripen quickly in the short summer of this district, with some very fine varieties of strawberries, black-currants, plums and apples.

The German invaders destroyed the greenhouses, laboratories, seed stores, dwelling-houses and other buildings on the station. Many collections of plants were taken away to Germany, and those that were left were badly neglected. People from neighbouring villages and some ex-marines are now helping to rebuild the station.

Under the guidance of Profs. Fedor Teterev and Roman Cordon, houses are being rebuilt and implements repaired. The plantations of shrub fruits and the orchards are being dug over. Seed is being prepared for rapid distribution. It is expected that in the autumn of 1944 and the spring of 1945 the Institute will provide farm nurseries with 100,000 strawberry cuttings, 50,000 young fruit trees, 60,000 currant bushes and many other plants. At the same time, rapid distribution of various plants is being organized so that by next summer some 3,000,000 saplings and cuttings of fruit trees and bushes will be ready. Extensive plans for scientific research work are also being made.

* Transcribed by A. Clifford.

## EARTHQUAKES DURING THE SECOND QUARTER OF 1944

DURING April and May, twenty-six strong earthquakes were registered by the instruments at Toledo (Spain), and ten by the seismographs at Wellington, New Zealand. In addition, twenty-five earthquakes were felt by people in some parts of New Zealand. During April 26–June 25, eight epicentres were determined from instrumental evidence by the United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association. On April 26 an earthquake originated at 1h. 53·9m. G.M.T. from a provisional epicentre at 1° S., 131° E., in western New Guinea. It was registered by the instruments at eleven United States observatories, and also at Toledo and Wellington. An after-shock from the same epicentre had its origin time at 14h. 37·9m. G.M.T. on April 27. This was registered at Toledo and Wellington and was reported from fifteen other stations in the United States, Australia and the Pacific Islands.

The earthquake of May 6 originated at 0h. 13·7m. G.M.T. from an epicentre at 22·4° N., 44·8° W., in mid-Atlantic. It was registered at nine American observatories and at Toledo, but not at Wellington, in any strength. The shock of May 25 at 1h. 06m. 39s. G.M.T. originated at 21·5° S., 179·0° W. in the Tonga Islands, with a depth of focus probably greater than 600 km. It has been reported from sixteen observatories in the United States, Pacific Islands, New Zealand and Toledo. This earthquake was world shaking, and attained a maximum ground amplitude at Toledo of 45 μ. Also on May 25 there occurred another shock at 12h. 58·1m. G.M.T. This time it was from an epicentre at 3° S., 152° E., in New Ireland. It was registered at fourteen stations in the United States, Pacific Islands, New Zealand and Toledo.

On June 16 an earthquake was registered at nine American observatories, and its epicentre as provisionally determined by the U.S. Coast and Geodetic Survey was at lat. 19° N., long. 105° W. Its origin time was 21h. 51·5m. G.M.T. The shock of June 21 originated in the New Hebrides (21·5° S., 169·8° E.) at 10h. 58·3m. G.M.T., and that of June 25 originated in mid-Atlantic (1° S., 25° W.) at 17h. 42·2m. G.M.T. according to the determination based on reports from Fordham, Huancayo, San Juan and Spring Hill.

In New Zealand the strongest earthquakes to be felt had strength IV on the modified Mercalli scale. These were reported as follows: April 17 at Porangahau, April 22 at Blenheim, Cook Strait and Wellington, April 30 at Tolaga Bay, May 16 in the Takaka region and May 20 at Rotorua. On May 9 an earth tremor was felt at Wairoa and Napier with scale III, and some inhabitants of Napier again felt a shock with scale III on May 31.

# FORTHCOMING EVENTS

*(Meeting marked with an asterisk is open to the public)*

### Saturday, September 30

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield 1), at 2.30 p.m.—Prof. F. C. Thompson: "Some Fundamental Work on Austempering and the Isothermal Transformation of Austenite".

### Monday, October 2

SOCIETY OF CHEMICAL INDUSTRY (YORKSHIRE SECTION) (at the Metropole Hotel, King Street, Leeds), at 6 p.m.—Dr. A. L. Roberts: "Drying by Infra-Red Radiation".

### Tuesday, October 3

CHADWICK LECTURE (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—The Rt. Hon. Lord Amulree: "Water Supplies in Peace and War".*

### Wednesday, October 4

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Dr. H. R. Fehling: "Thermal Insulation".

ROYAL ENTOMOLOGICAL SOCIETY OF LONDON (at 41 Queen's Gate, South Kensington, London, S.W.7), at 3.30 p.m.—Mr. E. D. Eyles: Film of House-fly Alighting on Ceiling.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Inaugural Meeting of the Micro-chemical Group; at 3 p.m.—Dr. Janet W. Matthews: "The Development of Micro Methods in Analytical Chemistry"; at 3.45 p.m.—Dr. A. A. Houghton: "The Micro-determination of Carbon by Wet Combustion".

### Thursday, October 5

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Sir Harry Railing: Inaugural Address.

### Friday, October 6

ASSOCIATION OF APPLIED BIOLOGISTS (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11.30 a.m.—Dr. J. W. Evans: "Applied Biology in Tasmania"; Dr. C. B. Williams: "Applied Entomology in South America".

### Saturday, October 7

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. A. D. Lacaille: "The Northward March of Palæolithic Man in Britain".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER AND DEMONSTRATOR IN GEOLOGY, with special qualifications in Mineralogy and Petrology—The Registrar, University College of South Wales, Cardiff (October 2).

PATENT AGENT of British nationality, preferably specializing in Electronics, by a well-established firm (subjects: mechanism, control apparatus, electronics)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2592.XA) (October 2).

PRINCIPAL of the Oldham Municipal Technical College—The Director of Education, Education Offices, Union Street West, Oldham (October 6).

PSYCHIATRIST (part-time) at the Child Guidance Clinic—The Chief Education Officer, Education Offices, York (October 7).

ASSISTANT MASTER with qualifications in CHEMISTRY at the Portsmouth Junior Technical School (evacuated to Salisbury)—The Education Offices, Northern Secondary School, Mayfield Road, Portsmouth (October 7).

LECTURER for ENGINEERING SUBJECTS to take two of the following: Preliminary Mathematics, Technical Drawing, General Science, in the Southampton Technical School—The Secretary, Education Office, Civic Centre, Southampton (October 7).

ASSISTANT (temporary) TO THE ADVISORY BACTERIOLOGIST—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (October 7).

BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Municipal Offices, High Wycombe, Bucks. (October 9).

SENIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No. E.902.A), and a JUNIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No. E.903.A) by the Sierra Leone Government—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (October 9).

ASSISTANT PLANT ENGINEER (Graduate in Chemical or Electrical Engineering, with experience in Design, Installation and Operation of Chemical Engineering Plant, including Small Electric Furnaces) in the Midlands—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2222.XA) (October 9).

SPEECH THERAPIST (full-time) for duties in the areas of the Bridgwater, Taunton and Yeovil Education Committees—The Clerk to the Taunton Borough Education Committee, Education Office, Municipal Buildings, Taunton (October 9).

ASSISTANT LECTURER (full-time) IN MINING in the Cannock Chase Mining College—The Director of Education, County Education Offices, Stafford (October 9).

LECTURER IN ENGINEERING IN WEST AFRICA—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.836.A) (October 15).

LECTURER IN PHARMACEUTICAL SUBJECTS in the School of Pharmacy—The Principal, Leicester College of Technology and Commerce, Leicester (October 19).

RESEARCH OFFICER in the Institute for Research in Agricultural Economics—The Secretary, Institute for Research in Agricultural Economics, Parks Road, Oxford (October 23).

TEACHER OF MATHEMATICS, mainly for work in the Day Technical School for Boys and in Day Classes for apprentices in the Technical Institute—The District Secretary, Kent Education Committee, 13 Tonbridge Road, Maidstone.

MASTER (or MISTRESS) to teach MATHEMATICS, chiefly in the Day Technical School for Boys—The Principal, Technical Institute, Tunbridge Wells, Kent.

CHIEF OF THE DEVELOPMENT DEPARTMENT—The Secretary, British Cast Iron Research Association, Alvechurch, Birmingham.

PHYSICIST OR PHYSICAL CHEMIST (young, man or woman) for research work on the Rheology of Dairy Products, especially Cheese—The Secretary, National Institute for Research in Dairying, Shinfield, Berks.

## COUNCIL FOR BRITISH ARCHÆOLOGY

THE inter-war period 1919–39, now so generally criticized for failures in the political and economic arenas, may be found in retrospect to be a Golden Age in the development of the science of field archæology in Britain, comparable with the period of rapid advance in the science of geology in the first half of the nineteenth century. Pitt-Rivers laid its secure foundations in the late nineteenth century, and in the years since his death there has never been lacking one or more men imbued with his ideas, and utilizing his technique; but whereas such competent workers were, up to 1919, in a minority, their practice was thereafter standardized and developed in respect of both excavation methods and record. Improved mechanical devices such as air photography and the Rolleiflex camera, and ease of access to remote places brought about by the motor-car and road improvement, were also contributory causes.

The results of improved transport facilities in particular are reflected in the published work of the period. The motor-car enabled middle-aged archæologists to be on a site distant from habitation during the whole period of the working day without physical exhaustion; a 'travelling' earthwork such as Offa's Dyke could be subjected without difficulty to the scrutiny of one individual throughout its length; and widely distributed examples of any specific type of ancient structure could readily be studied by one person in the course of a single summer holiday. Hence field survey, in advance of or correlated with excavation, has flourished exceedingly. Collaboration with students of the natural sciences, brilliantly illustrated, for example, in the palæobotanical field (pollen analysis), has aided the rapid advance in knowledge of Britain's unwritten history.

Under the leadership of the Society of Antiquaries of London, the Society of Antiquaries of Scotland, and the Congress of Archæological Societies (founded in 1888) programmes of research were, during the years under consideration, co-ordinated, and sites for excavation selected for their probable contribution to the solution of outstanding problems of a period or locality, though local initiative was never supplanted. The same period saw the remarkable growth in scope and range of the Ancient Monuments Branch of H.M. Office of Works, charged under the Ancient Monuments Acts of 1913 and 1931 with the guardianship and preservation of monuments in State ownership, and with the protection of specific sites (scheduled monuments) deemed of national importance, though in private ownership. During the period when Sir Charles Peers was chief inspector of ancient monuments, the governing principles and standards of preservation work were established; and these compare favourably with anything achieved elsewhere, though the safeguards against damage and destruction of scheduled monuments did not prove altogether satisfactory. The appointment of an archæology officer to the Ordnance Survey in 1921 led *inter alia* to the production of a remarkable series

of period distribution maps on a national basis; for example, long barrows and megaliths, Roman Britain, the Dark Ages. These illustrated the laws governing human settlement in early times—the relation of man to his environment—as expounded by O. G. S. Crawford and others, and now generally accepted by archæologists and geographers alike. Perhaps the main weakness during these years was a lack of understanding of the significance of these widespread activities, even on the part of the educated public, among whom the concept of archæology as a 'treasure hunt' still lingered.

The War has in part interrupted and in part modified this progress; field work has been undertaken of necessity, not of choice. Service and other departments have taken over large tracts of land, many of which included sites and structures of archæological interest, and these it was clear could not be preserved. Thus a unique opportunity was presented of excavating under State auspices, and at State expense, ancient sites thus accidentally involved. When the full story can be told, it will be realized that a great gain in knowledge and technical experience among field workers stands to the credit of the Ancient Monuments Branch of the Ministry of Works, which has organized this process of salvage, as well as to the Service departments for their enlightened and fruitful collaboration.

Conscious of the problems of the post-war years, archæologists have been stocktaking; a lively conference, held under the auspices of the Institute of Archæology of the University of London in August of last year, discussed "The Future of Archæology" at home (and abroad)*; divergence of views on the desirability of State help and control was noticeable, unanimity of view on the importance of education—the technical training of archæologists themselves and the diffusion of knowledge among teachers of the archæological approach to the past. One fact was at the back of all thoughts and all discussion of the future of archæology in Britain. As a result of bombardment, English cities of known antiquity have had great areas laid waste, London, Southampton, Exeter, Canterbury being outstanding examples, and plans for reconstruction may involve further demolitions. Thus the post-war period, as is now well recognized, offers a great opportunity, by the intensive study, prior to rebuilding, of the remains of ancient structures and stratified deposits in such areas, of recovering much of the history of our most important urban centres. This opportunity can never recur, for modern methods of construction of commercial buildings involve deep disturbance and removal of the relic-bearing accumulation of soil.

Hitherto there has been no central organization with a claim to speak authoritatively for British archæology as a whole, ranging from the study of Palæolithic man to that of his Victorian descendants, and the necessity for such an organization was now generally felt. On the initiative of the Roman Society, consultations were held during 1942–43 at the invitation of the Society of Antiquaries of London, under the chairmanship of the president, Mr. (now Sir) Alfred Clapham, and resulted in the formation of a Council for British Archæology, which held its first meeting in March, 1944. As at present constituted, it consists of upwards of a hundred members, representing national archæological societies, county and local societies regionally grouped, unive sities and colleges in which archæology is taught, national museums, the regional museums' federations, and certain societies with kindred interests: the Council has appointed an executive committee, organized its members into regional groups, and set up consultant panels of experts for periods from the Palæolithic to the Renaissance. It is also inviting the collaboration in an advisory capacity of persons eminent in the natural sciences. As a tribute to the status of the Society of Antiquaries of London and the particular services it gave in connexion with the formation of the Council, the first president, who will hold office for three years, will be the president of the Society, Sir Cyril Fox; the honorary secretary is Miss K. M. Kenyon, of the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1.

The Council is not intended to be an executive body; it will not undertake excavation. Its purpose is to ensure that archæological interests are not neglected in the future and to assist groups or individuals working to that end. It will, for example, urge the strengthening of existing measures for the care and preservation of historic buildings and antiquities, present a case for State aid in excavation as and when the magnitude of the task appears to be beyond the resources of existing societies' funds, and will co-operate, in its own field of interest, with the Museums' Association. It is pledged to work for the adequate recognition of archæology in the educational system of Great Britain and to further measures designed to enlighten the public concerning the records and monuments of the past. It will co-ordinate and facilitate the provision of expert advice on archæological matters. Its most urgent task will be to press upon the authorities concerned with reconstruction the importance of safeguarding archæological remains on sites affected by rebuilding or development; or if preservation is impracticable, of ensuring that scientific examination and record are made before destruction.

The first-fruits of the Council's work are already in evidence. An independent committee for Roman London has been formed, a deputation from which has been received by the Lord Mayor, to consider the many and various problems of the remains of *Londinium*, the great commercial and administrative centre that was the City's precursor, which lie some 20 ft. below present-day street-levels. But effective official and corporate action in these important matters, as in others with which the Council is concerned, depends ultimately on the sanction of public opinion, and the urgent need of educating the public is fully recognized.

Unenlightened persons may have argued that archæology has no practical value and that after the War all efforts should be devoted only to 'things that matter'. But archæology, especially of the earlier

* Occasional Papers, No. 5: University of London, Institute of Archaeology. Pp. 100. See also *Nature*, 152, 320 (1943).

periods, will surely be of real and practical value in the post-war world from two points of view. In the first place, it is an almost ideal hobby study, and a democracy which is ever reaching towards more pay and shorter hours of work must be careful to further intellectual leisure occupations. Field work in archæology can be undertaken during holiday periods and useful evidence exposed by many ordinary folk who take the trouble to undergo a not too arduous course of training. Thus can archæology contribute to that cultural training which is so essential alongside other social disciplines as distinct from the more direct vocational studies.

But more important still is the fact that in the study of archæology, particularly of prehistory, science and humanity meet: the subject is man, yet the methods of work and the discipline are strictly scientific. As a training for the young it is therefore ideal—the human interest is always there, and their minds are broadened by the problems and other subjects they are brought up against during their work, while the whole approach to the subject and to others, like geology, which are involved is scientific. It has indeed been urged that archæology should be included in the curricula of secondary, and even of senior, schools. This would involve the training of a number of teachers, but it is a goal well worth aiming at. One way to start the ball rolling would seem to be to urge on the commissioners in charge of the Civil Service schedules for entrance examinations the wisdom of including archæology among the optional subjects. Many of these are now included to test the mental capacity of the candidate rather than for their practical usefulness in the service he is entering, and archæologists can indeed claim that their subject is ideal from this point of view.

Once recognized by the Civil Service as an examination subject, those who regulate the schedules for the higher certificate examinations of schools, and even for the humbler school certificates, would quickly turn their attention to the problem of including it in their programmes too. Here would be a splendid opportunity for the new Council to help by urging the Government to give the lead. The fact that several eminent Civil servants are on the Council will ensure that its requests to authority are practical.

So also might the universities, in their post-war replanning of courses, consider archæology as a subject of study for those students in the faculties of science and arts and in the training departments who are not making the subject their principal study; for thus can archæology help to widen the scope of university studies.

In this and in the other ways already outlined it will be excellent if the newly formed Council will tackle the problem of educating the nation to the importance of the subject of archæology and of gaining official recognition thereof. This, together with its concern for the safeguarding of ancient sites and the co-ordination of archæological effort, will cause every archæologist, inarticulate spade-worker and ready-penned publicist alike, to welcome its formation as filling a need of which they have long been conscious.

# DYNAMICS OF SOCIAL SECURITY

## The Price of Social Security

By Gertrude Williams. (International Library of Sociology and Social Reconstruction.) Pp. vii+199. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1944.) 12s. 6d. net.

MRS. GERTRUDE WILLIAMS' book is as topical as its title suggests, but on other counts than would appear on the surface. It is in reference to the White Paper on Employment Policy that its significance chiefly lies; but it closes with a sound and constructive criticism of the Civil Service which is equally pertinent to discussion of the Assheton Report on the Training of Civil Servants. Fundamentally, the book is a study of the mobility of labour and, cogently as Mrs. Williams argues that a new mobility of labour must be part of the price to be paid for social security, it may well be doubted whether the emphasis placed by Sir William Beveridge on labour mobility, and on the selection and training of staff for the Ministry of Social Security with special regard to the functions of serving the public and understanding the human problems with which they will be concerned, is likely to reconcile those who purchase the book on the ground of their interest in social security or to find an answer to the question: Can we afford social security?

It would be unfortunate if such disappointment prejudiced the success of such an excellent exposition. Mrs. Williams is an able chronicler, and her descriptive writing is clear and not obscured with unnecessary detail. She has the knack of bringing out the main points and avoiding irrelevancies, and even the disappointed enthusiast for the Beveridge Plan should be grateful for the indications given of fundamental changes in our industrial structure which have a profound bearing on the practicability of that full employment policy which is postulated as Assumption C in the Beveridge Plan.

If the title is misleading, it is not irrelevant. Mrs. Williams is not concerned with the financial aspects of social security but with the economic, social and industrial consequences. She emphasizes the danger that improved social services may harden the arteries of the economic system. We have given up one set of incentives without even facing the fact that we need something to take their place, and her discussion of the psychological problems of adapting incentives to work to a changing world, and of how far a sense of social obligation can supersede hunger as a spur to effort, leads to the conclusion that we must pay the price of social security by instituting in peacetime as in war some degree of State control over occupational distribution.

The first three chapters of the book, in which Mrs. Williams analyses the factors which impede the mobility of labour, should be widely read as an exposition of the argument condensed into the sections on distribution of labour and mobility of labour in the White Paper on Employment Policy. The Government could desire no better justification for its arguments than this able study of the reasons why labour should be fully and continuously mobile if we are to take advantage of the opportunities given us by improved techniques and new knowledge, and why, on balance, mobility has decreased in spite of some factors tending towards its increase. The provision of maintenance during employment has reduced the urgency of the need for finding new

employment and thereby clogged the economic mechanism through which changing wage-levels affected the occupational and geographical redistribution of labour. The general effect of inter-war developments in unemployment maintenance has been to remove one set of incentives to work without replacing it by another, and in Great Britain we have only now, in the White Paper, faced the fact that we need something to take their place.

The mobility of labour is of course only one aspect of the problem of productivity or of full employment, but Mrs. Williams does not suggest that the price of social security is something to be paid by employee or employer only in the acceptance of compulsion or direction in peace-time. Equally important is the analysis, in her next two chapters, of labour control in war-time in Britain and of labour control in Germany and the U.S.S.R., which leads to the exposition in her final chapter of the administrative spade work that must precede any attempt to perpetuate labour controls in peace-time. The price of social security has to be paid in sound administration as well as in the acceptance by the individual of restrictions on freedom of choice of occupation, until the sense of social obligation is as powerful, and as unconsciously accepted, as is an underlying principle of conduct such as self-interest.

Despite Mrs. Williams' pragmatic approach to her subject, she is stronger at analysis and in defining the problem than in constructive suggestions for dealing with it. She stresses the importance of the educational approach to the development of new incentives, and senses the opportunities in the Government training centres, the Army Bureau of Current Affairs, the employment exchanges and the joint production committees, and her clear exposition makes the book highly stimulating to the imaginative reader. Much more might be done, as she indicates, in the way of vocational selection by utilizing the data in this field now being accumulated in the Forces. Again, Mrs. Williams points out that compulsory transfer to other jobs involves acceptance by the State of some measure of responsibility for welfare arrangements and wage standards.

The best part of this chapter is that in which, developing further ideas she has already voiced in the chapter "The Staff Problem" contributed to the volume "Social Security" edited by W. A. Robson, she discusses the reform of the Civil Service, which must also form part of the price of social security. Constructive long-term thinking and the exercise of the newer mental disciplines, she urges, is a Government function of the first importance. Here again, in pleading the importance of intelligence and statistics as a prelude to scientific policies based on known facts, she is in line with the White Paper; but in analysing the requirements of a Civil Service capable of integrating the work of the Ministries with the wider life of the community, she sees that it is not only in the Civil Service that reform is called for: a high standard of Ministerial statesmanship, she says, is the essential foundation of successful Government control, whether of labour mobility or of any other communal activity.

The similarity of thought and argument here is very close indeed to that of a recent admirable article in the *Political Quarterly* on "Government Administration and Efficiency" in a series on the post-war machinery of government. The analysis is of special interest in view of the recent report on the training of Civil servants, and elaborates further some points that are imperfectly covered in that report. In a single paragraph, Mrs. Williams anticipates a number of the more important recommendations of the report, but on the whole, within the limits of her argument, she is even more searching and suggestive.

This, then, is a book that is well written and should be well read. It has merits as a mere chronicle of developments in a comparatively limited economic field. It is even more valuable in its suggestions as to the way in which such institutions as industry, the trade unions and the Government machine must adapt themselves to the new functions that must be covered in an attempt to establish full employment and social security. For the rest, it has claims on the interest of the scientific worker as indicating what is involved in the elaboration of scientific policies and the application of the scientific method in human affairs. Further, within the limits to which she confines herself, Mrs. Williams has given a modest but no less admirable stimulant to the constructive thinking about the organization and administration of social and economic institutions on which the development, if not indeed the survival, of our democratic system depends. R. BRIGHTMAN.

## A NATURALIST IN THE HIGHLANDS

### Highland Naturalist

A Gamekeeper's Observations and Discoveries. By Dugald Macintyre. Pp. 240+8 plates. (London: Seeley, Service and Co., Ltd., n.d.) 12*s*. 6*d*. net.

DUGALD MACINTYRE is a Highland naturalist who has made his name as one of the leading observers of his time. He has during his long life had unusual opportunities for recording the habits of bird, beast and fish, and in him is the rare combination of the accurate recorder and the man who can set down clearly, simply and truthfully what he has seen and heard. Therefore, any book by Dugald Macintyre is of value.

In this volume the author weaves his observations into a number of short chapters. In each chapter is told the story of the life-history of some bird, animal or fish, and in that story are embodied the author's own observations.

We read (p. 80) of a gannet which, when diving for fish, pierced a guillemot right through with its sharp bill. Unable to rid itself of the dead guillemot, the gannet drifted about and finally came ashore exhausted, when a good human friend cut away the guillemot and thus saved its life. We read of a white grouse which, although a cock bird, was flushed from a nest he was making, while his mate had laid her first egg in her own nest close by. We read (p. 98) of the old white grouse actually dying as the author passed—falling from his roosting place on the steep hill-face and rolling past Dugald Macintyre in the dusk of a frosty winter's evening. The author attributes the old grouse's death to heart failure following on grouse disease. There are statements in this book which are difficult to check, and which in a naturalist of less standing might be looked upon with reserve. But in one of his earlier statements, no less surprising, Dugald Macintyre has been fully vindicated. It was in March 1913 that he wrote to the *Field*, saying that the common curlew was in the habit periodically of ejecting the lining membrane of

its gizzard by coughing. These lining membranes are light yellow pouch-like objects with the consistency of thin rubber, rolled up by the muscular coat of the gizzard wall before ejection. To Mr. Macintyre falls the credit of being the discoverer of this curious habit, now well attested.

The author, in a short chapter on the kite, suggests that it might be possible to reintroduce this bird into Scotland by placing its eggs in buzzards' nests. It is possible that, were a sufficient number of kites' eggs available, this might be done, but in Wales, the last nesting haunt of the species in Britain, the kite is still so scarce that I am very doubtful whether a clutch of eggs would be spared for the experiment. That is also the difficulty in the re-introduction of the osprey in the Highlands—the rareness of its eggs. Were some wealthy ornithologist to transport by air after the War a clutch of fresh osprey's eggs from Scandinavia to Scotland, and were these eggs to be placed in a nest of a buzzard already earmarked for this purpose, a brood of ospreys might be reared that would re-populate some Highland loch where the species formerly nested.

Mr. Macintyre is a keen angler, which is not surprising when one remembers his distinguished Highland ancestry. He is familiar not only with salmon, sea trout and brown trout, but also with the fish of Highland sea lochs and of the Atlantic. He describes the life-history of a pollack (or lythe as it is named in Scotland) which when caught turned the scales at 19 lb. That is a great weight for a pollack, but the fishermen who at times fish for these strong fish around the ocean rock of Sgeir nam Maol, in the Minch off northern Skye (where the owner of an ocean-going yacht told me that he caught heavier lythe than anywhere else off the British coasts) say that a 20-lb. lythe is not unknown here. My heaviest lythe was just over 16 lb., and my wife caught one of 16½ lb., but recently these fish have been much smaller.

Seton Gordon.

## COMMERCIAL FORESTRY IN THE UNITED STATES

**American Silvics and Silviculture**

By Prof. Edward G. Cheyney. Pp. x+472. (Minneapolis: University of Minnesota Press; London: Oxford University Press, 1942.) 30*s*. net.

PROF. EDWARD G. CHEYNEY has written in this volume a very useful and comprehensive compilation on the American aspects of the sylviculture of some hundred and fifty commercially important forest species. His book is said to be—and many will agree—the first attempt at treating this branch of forestry in America from the fully practical side. Sylviculture, he explains, has been developed in Europe as an art through centuries of experience with European species of trees. "Out of that experience has come a series of silvicultural patterns that can be useful in America when we have learned to adapt and apply them to our own species. In themselves the patterns mean but little. To use them we must have knowledge of the factors that influence the growth of trees in competition with each other, of the types in which American species group themselves, and of the silvical characteristics of our more important species." It has been the aim of the author to deal as fully as present information permits with his definition, and his book discloses how admirably he has carried out his object.

In connexion with sylviculture as gradually developed in Europe, the author correctly says that what he terms the sylvicultural patterns, that is, the various sylvicultural systems, will have to be adapted in order to apply them to American species. The recognition of this important factor applies, where forestry is one of the national assets, to almost every country in the world outside Europe. India would appear to be the first country to which this realization, through its Forest Service, came—but only after a period of years during which rigid copies of purely European practice had shown their fallibilities. In that country for many years past the sylviculturist has recognized the necessity of modifying and adapting to local and varying conditions the text-book definitions, perfectly sound ones for Europe, of the sylvicultural systems. It appears curious, therefore, that Prof. Cheyney, in the careful research and consideration he has given to his subject, should have apparently ignored the great amount of work carried out in this direction throughout India and Burma during the past forty years. It is the reviewer's belief that America could find some adaptations or modifications of the systems now adopted in India as forms of practical management which could be of use to conditions in parts of the country, especially in the transition from virgin forest to a forest under a correct and detailed management.

The book is divided into four parts. The first three are written as a text-book on forestry. Part 4 deals with the sylvicultural description of all the important species. In Part 1, sylvicultural factors are dealt with. Part 2, which is very informative, discusses the forest regions of the United States under forests of the Northern Region, forests of the Appalachian Region, forests of the Atlantic and Gulf Coastal Plains, forests of the Lake States, forests of the Rocky Mountains, forests of the Northern Pacific Coast and forests of the Southern Pacific Coast. Part 3 treats of sylviculture in its elementary aspects, the sylvicultural systems, the application of the systems to the various forest types, thinnings and the disposal of slash. In Part 4 the species of trees given alphabetically are dealt with under range, types and associates, soil, moisture, light, and seed-production, growth management and resistance (to fire, pests and so forth).

In America, Prof. Cheyney's book is hailed as the first attempt to place sylviculture in its application to a correct management of the forests in its practical position. "His book deals with American sylviculture and constitutes the only discussion of its kind."

It is rightly said that the natural forests of the United States have contributed greatly to the country's development. It is equally true that in the past they have been greatly and often ignorantly exploited by the lumberman, with at times disastrous after-effects. Unfortunately this type exploitation has not ceased. "In the first year of World War II," it is said, "three-fourths of the entire cut lumber of the United States was absorbed by the War effort. All this indicates the immediate need for better forest management." In spite of the above statement, paper stocks are obviously still fairly abundant, for Prof. Cheyney's book is beautifully got up and is illustrated by many photographs lent for the purpose by the United States Forest Service.

E. P. Stebbing.

## On the Influence of Trades, Professions, and Occupations in the United States, in the Production of Disease

By Dr. Benjamin W. McCready, 1837. (Publications of the Institute of the History of Medicine, the Johns Hopkins University, Fourth Series: Bibliotheca Medica Americana, Vol. 4.) Pp. vii+129. (Baltimore, Md.: Johns Hopkins University, 1943.) 1.75 dollars.

THE study of industrial diseases is a subject which, for obvious reasons, received little attention from medical men until comparatively recent times. Bernardino Ramazzini's "De morbis artificum diatribum" of 1700 was the first comprehensive work on occupational diseases, and the second was that of Thackrah of Leeds published in 1831. This latter work and the growth of industrialization in the United States of America influenced the Medical Society of the State of New York to propose for a prize essay in 1835 the subject of "The influences of trades, professions and occupations in the United States in the production of disease". The winner of the prize was a twenty-three year old physician, Benjamin W. McCready, and his essay was first published in 1837. This book contains the original essay with a critical historical introduction by Genevieve Miller.

The essay consists of four sections, discussing thirty-one employments. The first deals with outdoor workers in agriculture, on canals and railways, labourers and seamen; the second describes the workers in the textile industry; the third deals with artisans and tradesmen; and the fourth with the professional men.

McCready saw that in many cases the industrial hazards of his day were caused as much by basic habits and environmental conditions as by any immediate dangers in the occupations. The remedies he proposed were simple—proper housing and ventilation, personal cleanliness, shorter working hours and more exercise.

The editor and publishers are to be congratulated on their reproduction of this important historical document.

## Civilization and Disease

By Prof. Henry E. Sigerist. Pp. xii+255+29 plates. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1943.) 22*s*. 6*d*. net.

DISEASE has played a great part in the evolution of civilization. Dr. Sigerist develops the theme and demonstrates the interrelationship in its many aspects in the course of human history. He begins by describing the influence of external factors of living conditions, clothing, lighting and nutrition on the genesis of disease, and then passes on to particulars. Economic and industrial changes and their effects on the character of disease are illustrated by reference to the works of Ramazzini, McCready and Thackrah. The position of the sick in society has greatly changed from the earliest days, when they were ostracized as in the case of lepers or horribly confined if mentally ill. In the complex modern society, many sick persons can usefully be employed in selected occupations.

The law appears in the establishment of quarantines, in the licensing and regularization of medical practice, and in public health and industrial organization.

The course of history has at all times been subject to influence by disease in epidemic form, and reference is made to the effects of plague, typhus and malaria on the results of battle and on distribution of population.

Towards the end, Dr. Sigerist becomes discursive and sketches over the relationship between religion, metaphysics, science, the arts and disease.

The subject-matter of this book was first used as a series of lectures, and this is apparent in the style. The wideness of scope and paucity of detail make this very readable book more suitable for the sociologist and lay reader than for the student of the history of medicine. The volume is beautifully produced, and has excellent and interesting illustrations.

## Thermionic Valve Circuits

By Dr. Emrys Williams. Second edition. Pp. viii+207. (London: Sir Isaac Pitman and Sons, Ltd., 1944.) 12*s*. 6*d*. net.

THE first edition of this book was reviewed in *Nature* of July 18, 1942. According to the author's preface: "The appearance of a second edition of this book has been hastened by the extensive consumption of the first edition by the enemy Luftwaffe". The opportunity has been taken to increase the size by some 15 per cent, by a general expansion of the existing chapters. New material has been added dealing with such subjects as frequency modulation, gas-filled valves, time bases, the Kipp relay, the transitron and the cathode follower; but the author has rightly resisted any inclination to go too far in meeting the general criticism of incompleteness. The book remains a very good survey of all the main types of valve circuits, presented in such a way that the student may be in a position to understand, or even foresee, further developments.

## Pacific Ocean Handbook

By Eliot G. Mears. Pp. viii+192. (Stanford University, Calif.: James Ladd Delkin, 1944.) 1 dollar.

PROF. ELIOT G. MEARS, professor of geography in Stanford University, set himself a formidable task in compressing into less than two hundred small pages a survey of the current scientific knowledge of the Pacific Ocean and its adjacent lands. There are chapters on the structure of the basin, its islands, on the physical aspects of the waters including drifts and currents, and on every aspect of the climate and particularly the storms. Other chapters deal with navigation, magnetism and tides. All sections are amply illustrated with maps. When such a degree of condensation is demanded, minor slips are unavoidable; but on the whole the little volume is most informative on the scientific side and includes results of much recent work. There are also statistical appendixes and a folding map.

## Textbook of Histology for Medical Students

By Dr. Evelyn E. Hewer. Third edition. Pp. xii+364. (London: William Heinemann (Medical Books), Ltd., 1944.) 17*s*. 6*d*. net.

THE essentials of normal histology are simply stated in this short text-book. The illustrations are excellent, and the photomicrographs by E. V. Willmott deserve special mention. As a laboratory reference book for medical students engaged on practical histology or preparing for examinations, this could not be bettered.

# SOCIAL AND INDUSTRIAL INSURANCE IN GREAT BRITAIN

ALMOST two years after the publication of Sir William Beveridge's report on Social Insurance and Allied Services, the Government has issued two White Papers, Part 1 dealing with its proposals for social insurance generally (except for industrial injury) and for family allowances, and Part 2 with proposals for replacing the existing system of workmen's compensation by a new scheme of industrial injury insurance. The whole scheme follows the lines indicated by Sir William Beveridge more closely than the prolonged delay had led many to expect.

## Social Insurance

In introducing the proposals for social insurance (Part 1)* the White Paper states that the Government accepts as necessary prerequisites to an improved and comprehensive plan of social insurance the three assumptions on which the Beveridge plan was based: institution of a scheme of children's allowances; framing of a comprehensive health service; and the avoidance of mass unemployment. Proposals for a national health service have already been published, and the Government's policy for maintaining a high and stable level of employment after the War has been set forth in the White Paper on Employment Policy. Those for a scheme of family allowances are included in the present paper.

These proposals are based upon two principles: first that nothing should be done to remove from parents the responsibility of maintaining their children; and second, that it is in the national interest for the State to help parents to discharge that responsibility properly. The scheme is not intended to provide full maintenance for each child but is a general contribution to the needs of families with children. This purpose, in the Government's view, can best be attained if a substantial part of the benefit is given in kind, and the school meals and milk services will therefore be extended to make them available to pupils in primary and secondary schools in receipt of grant from the Ministry of Education or the Scottish Education Department. These benefits in kind will be free of cost to the parents and will be available to all children in a family attending school, including the first.

The cost to public funds of supplying meals and milk to children at school when the service has reached its full development is estimated at about £60 millions a year. While accepting the argument in the Beveridge Report that children's allowances should be non-contributory and met wholly out of taxation, and that no allowance should be paid in respect of the first child, the Government rejects the rate of 8*s.* a week suggested by Sir William Beveridge and proposes a weekly cash allowance of 5*s.* for all children after the first below school-leaving age and remaining at school until July 31 following their sixteenth birthday. When the parent is receiving benefit, 5*s.* will be added to the benefit in respect of the first child.

With the exception of this family allowance scheme, the Government has adhered to the principle that freedom from want must be achieved in the first instance by social insurance: benefits must be earned by contributions. It has also decided not only to increase the range and amount of benefits provided, but that the scheme as a whole shall embrace the entire population. Of the six fundamental principles on which the Beveridge plan was based, the Government has adopted five: flat rate of contribution; flat rate of subsistence benefit; unification of administrative responsibility; comprehensiveness; and classification. There has been no attempt to vary contributions with the earnings of those who make them: broadly, the principle adopted has been that of equal benefits for equal contributions. Contributors and beneficiaries are classified into six groups, differing in respect of the benefits they need and the contributions they must make to receive them. Adopting the principle that the administration of a single, comprehensive, universal scheme of social insurance must be unified and that the various unco-ordinated sections of the system of to-day must be brought within a single administrative framework, the Government proposes the establishment of a Ministry of Social Insurance responsible for the whole of social insurance. The administration of assistance will be kept separate from that of insurance, though the Minister of Social Insurance will be responsible to Parliament for both. The present responsibilities of public assistance authorities for the payment of assistance in cash will be transferred entirely to the Assistance Board.

The Government has not accepted the sixth principle of adequacy of benefit. In fixing the rates of benefit, the Government considered whether it would be practicable to adopt a subsistence basis for benefits, but has rejected this as impracticable on the ground that the linking of benefit to subsistence-rates might involve the frequent variation of benefit-rates in accordance with the cost of living, and also that social insurance must necessarily deal in averages of need and requirement. A high level of benefit must mean a high level of contribution, and the Government concludes that the right objective is a rate of benefit which provides a reasonable insurance against want and at the same time takes account of the maximum contribution which the great body of contributors can properly be asked to bear. There still remains the individual's opportunity to achieve for himself in sickness, old age, and other conditions of difficulty a standard of comfort and amenity which it is no part of a compulsory scheme of social insurance to provide. In reserve there must remain a scheme of national assistance designed to fill the inevitable gaps left by insurance, and to supplement them where an examination of individual needs shows that supplement is necessary. There is no reference to a unified means test as advocated in the Beveridge Report, but the supercession advocated in the latter of the present system of approved societies is accepted: the Government concludes that it is not practicable to retain 'approved societies' either as independent financial units or as agents in the administration of the scheme. The considerations leading the Government to this conclusion and the alternative proposals of the Report, together with the wider proposals submitted on behalf of the approved societies, are summarized in Appendix II of the White Paper.

The scheme proposed by the Government is compulsory and includes everybody. The population will be divided into six classes: employees; the self-employed; housewives; adults who do not earn; children; and people over working age. It thus applies to large categories not hitherto covered

* Social Insurance. Part 1. (Cmd. 6550.) Pp. 64. (London: H.M. Stationery Office, 1944.) 6*d.* net.

by insurance; for example, those living on earnings gained otherwise than by salary or wages, or on earnings above £420 a year or on private income, and those employed in professions or industries hitherto specially excepted. Each insured person will pay a single weekly contribution for all benefits in the form of one stamp on a single document. For employed persons the stamp will also include the contribution for insurance against industrial injury. The first, second and fourth will be the contributing classes, and the rates of weekly contribution for persons over 18 (covering for Class I the benefits under the Industrial Injury Insurance Scheme as well as the Social Insurance Scheme) will be:

| | Class I | | | Class II | Class IV |
|---|---|---|---|---|---|
| | Insured Person s. d. | Employer s. d. | Total s. d. | s. d. | s. d. |
| Men: | | | | | |
| Aged 18 and over | 3 10 | 3 1 | 6 11 | 4 2 | 3 4 |
| ,, 16–18 | 2 5 | 2 1 | 4 6 | 2 9 | 2 2 |
| Women: | | | | | |
| Aged 18 and over | 3 0 | 2 5 | 5 5 | 3 6 | 2 8 |
| ,, 16–18 | 2 0 | 1 7 | 3 7 | 2 5 | 1 10 |

There will be a standard rate of benefit of 40*s*. a week for a married couple and 24*s*. for a single man or woman, with lower rates for those less than 18. Sickness benefit will end after three years of continuous disability, and invalidity benefit at the standard retirement pension will be substituted. Unemployment benefit will be paid up to a limit of thirty weeks in a continuous period, together with additional days where the contributor has a good record of employment. After the end of either benefit, further contributions must be paid before an insured person can re-qualify for benefit. Special allowances at a higher rate will be available to persons undergoing a course of approved training, but such training allowances will not form part of the social insurance scheme but will be paid out of taxation. There is no condition, as in the Beveridge plan, of unemployment benefit being subject after a certain period to attendance at a work or training centre, and this, like the limitation of benefit, is a marked break from Sir William Beveridge's proposals.

With regard to the self-employed, the difficulties of securing effective control over the payment of benefit are emphasized, as in the Beveridge Report, but the Government proposes to pay benefit to Class II contributors after four instead of after thirteen weeks, and to excuse payment of contributions during those four weeks. An additional allowance of 16*s*. a week will be paid to those on single benefit who have an adult dependant. There will be a standard rate of retirement pension of 35*s*. for a married couple and 20*s*. for a single person. These rates will take effect from the commencement of the scheme instead of starting at 25*s*. and 14*s*., respectively, and increasing to the full rate of 40*s*. and 24*s*. after twenty years as recommended in the Beveridge Report. The pensionable age will be sixty-five for men and sixty for women, but the joint pension will become payable when the husband qualifies, provided that if the wife is less than sixty years old, she is not gainfully occupied. Pensions will be paid only to those who have retired and will be reduced if more than 20*s*. weekly is earned during retirement. They will also depend on contributions paid during the working life of the applicant, and will be reduced when the contribution record shows a deficiency. Pensions will be increased by 2*s*. a week (joint) and 1*s*. (single) for each year of work after retirement age. Special arrangements will be made covering persons already pensioned or insured when the scheme comes into operation.

For married women, additional benefits will be available, subject to certain qualifying conditions, in a maternity grant of £4, maternity benefit at the rate of 36*s*. a week for thirteen weeks for gainfully occupied women, provided that occupation is given up for that period, or for women not eligible for maternity benefit, an attendant's allowance of £1 a week for four weeks. Special provisions will enable married women to insure for a personal retirement pension of 20*s*. a week in lieu of their share in a joint pension, and enabling married women earning more than 20*s*. a week to insure for sickness benefit at the rate of 16*s*. a week and unemployment benefit at 20*s*. a week. The main provisions for widows will be a benefit of 36*s*. a week, with 5*s*. added for the first child, during the first thirteen weeks of widowhood. Thereafter, if there is a dependent child, a guardian's benefit of 24*s*. a week, with 5*s*. added for the first or only child, and a widow's pension of 20*s*. a week to widows who are fifty or over when the husband dies or when the children cease to be dependent, provided ten years have elapsed since the marriage. These benefits will terminate on remarriage, and the last two will be reduced for substantial earnings.

Death grants will be paid at the rates recommended in the Beveridge Report according to the age at death, but an age limit of sixty-five instead of sixty is proposed, when one grant will be paid at the beginning of the scheme, and for persons then between fifty-five and sixty-five the grant will be £10. Such questions as insurance for indirect expenses connected with funerals are reserved for separate examination. Sickness and invalidity benefit, maternity benefit, widow's benefit, guardian's benefit, widow's pension and retirement pension will be reduced by 10*s*. a week during maintenance in hospital after the first twenty-eight days of such maintenance. Not more than any one social insurance benefit or pension will be payable to an individual at any one time.

Apart from the question of workmen's compensation, the Government in its scheme has accepted outright sixteen out of the twenty-three changes proposed in the Beveridge Report; and with modification or reserve two of the others. Essentially the scheme may be described as on a practical basis. The refusal to make disability benefit indefinite in duration or unemployment benefit at full rate indefinite in duration but conditional on attendance at a work or training centre after a limited period, like the rejection of a subsistence basis for benefits, shows that the Government has not adopted the basic philosophy of the Beveridge Report; but there can only be the warmest welcome for proposals which sweep away so many anomalies, and simplify and unify administration and rates of benefit and contribution. It will be noted that the administrative organization outlined is framed to meet the position at the beginning of the new scheme, and that it is proposed to review the position when the scheme is in operation and administrative policy clearly defined and established.

## Industrial Insurance

Whatever slight disappointment may be felt in some quarters with the Government's proposals for social insurance as lacking the boldness of the original Beveridge Report, and keeping more strictly to the

actual abolition of want, no charge of lack of boldness can be brought against the proposals for an industrial injury insurance scheme outlined in the White Paper issued as "Social Insurance. Part 2: Workmen's Compensation"*. The need for radical reform of the present situation is frankly accepted, and the proposals advanced are in some respects an improvement on the Beveridge scheme. They are intended to avoid the main weaknesses and difficulties of the existing system and to remove workmen's compensation from the atmosphere of controversy and conflict with which it has been surrounded and establish it on a happier and sounder foundation.

The White Paper gives first a concise summary of the present system of workmen's compensation in Great Britain, first established in 1897, followed by a survey of the proposals on this question in the Beveridge Report and a concise statement of the Government's views. Generally, the Government endorses the criticisms of the existing system made in that report. In particular, it considers that the Beveridge scheme is too complicated and allows too much scope for contention between the workman (or his trade union) and the employer (or the insurance company or mutual association with which he is insured); it thus tends to retard the workman's recovery and to prejudice good relations between him and his employer. The Government considers it essential to provide that, in future, claims should be made on an independent authority and settled by a procedure less liable to give rise to friction. Accordingly it reaches the general conclusion that the present system should be replaced by a new scheme, the general structure of which should be based on the accepted principles of social insurance.

Proceeding on this basis, the Government agrees with the proposals in the Beveridge Report that the new scheme, broadly speaking, should apply to all persons working under a contract of service, including non-manual workers, and without any income limit; that the cost should be borne by a central fund maintained by contributions from employers and workmen, with a contribution from the Exchequer; that claims should be dealt with by administrative rather than legal procedure; and that the responsibility for the general administration and supervision of the working of the scheme should rest on the authority responsible for the general scheme of social insurance. It is unable, however, to accept four of the main proposals of the Beveridge Report for the reasons indicated below.

First, the Government does not think it right to limit special rates of benefit for long-term disability to cases of more than thirteen weeks duration. Such cases constitute not more than 10 per cent of the total, and the Government thinks the advantage claimed for unification of rates during an initial period is exaggerated. Secondly, the proposal to relate industrial pensions for long-term disability to the earnings of the workman before the accident in cases of total incapacity, and to his earnings both before and after the accident in cases of partial incapacity, is regarded as contravening the principle that there should be differentiation in benefits only according to family responsibilities, and that subject to provision for such responsibilities, there should be uniform flat rates of benefit in return for uniform flat rates of contribution. Further, the assessment of workmen's compensation by reference to earnings has given rise to serious difficulties and objections which are considered in some detail in the White Paper.

The Government therefore proposes to adopt two entirely new features for the assessment of industrial pensions: (*a*) to provide, in accordance with the generally accepted principle of social insurance, uniform flat rates of pension without regard to pre-accident earnings, but taking account of family responsibilities; and (*b*) to give benefit according to the degree of disablement due to the injury in the same way as is done under war pensions schemes, through assessment by a medical board of the condition of the workman resulting from the injury as compared with the condition of a normal healthy person of the same age and sex. This principle has the advantage of getting rid of the distinction hitherto drawn between total and partial incapacity for work, and giving the workman who has suffered an injury causing permanent or prolonged disablement a pension commensurate with the assessed degree of disablement, irrespective of his earning capacity. It eliminates as a cause of dispute the questions whether or to what extent the workman has recovered his earning capacity. It removes the grievance that an improvement in earning capacity results in an automatic reduction of compensation, and avoids any ground for suspicion on the part of the workman that he is being pressed to return to unsuitable work with a view to such reduction, and the fear that if he returns to work he will jeopardize his right to further compensation. It should also remove any hesitation he may feel in submitting to a course of rehabilitation treatment and thus promote a speedier recovery, while it helps to meet the complaint that no compensation is paid for mutilation or disfigurement except in so far as it causes loss of earning capacity.

Thirdly, the Government does not agree with the proposal in the Beveridge Report that special provision in fatal cases resulting from industrial accident or disease should be by way of the grant of a lump sum. Such payments, even if administered under strict control, are not a satisfactory method of assuring an income, and the Government considers that provision for dependants in fatal cases should be by way of pension or weekly allowance. Fourthly, the Government does not accept the proposal that a substantial part of the fund for payment of benefits should be found by means of a special levy on employers in the hazardous industries. This proposal constitutes a departure from the complete pooling of risks adopted generally in other branches of social insurance. "Hazardous industries are not hazardous because employers in them are less active in the prevention of accidents than other employers, or because the workmen in those industries are less careful than other workmen. They are hazardous because of the nature of the employment and the inherent risks." The Government questions the value of the incentive to the prevention of accidents ascribed to the merit rating system suggested in the Beveridge Report, and considers that for further progress in this matter we should look to the development of the standards set up under the factories, mines and other safety enactments, and to the increase of co-operation between employers and workmen. On the other hand, the Government would welcome the establishment of joint bodies for dealing with safety questions—either statutory or voluntary—in all industries where there are substantial risks

* Social Insurance. Part 2: Workmen's Compensation. Proposals for an Industrial Injury Insurance Scheme. (Cmd. 6551.) Pp. 32. (London: H.M. Stationery Office, 1944.) 3*d.* net.

of industrial accident and disease. It also agrees with the recommendation in the Beveridge Report that an inquiry is desirable into the relation, both in industrial and non-industrial cases, between claims to security benefit and claims for damages in respect of personal injury caused by negligence, and also a review of the law governing the liability of employers and third parties to pay damages or compensation to workmen, or their legal representatives and dependants, independently of the provision for them proposed in the new scheme; the Government has set up for this purpose a committee with comprehensive terms of reference under the chairmanship of Sir Walter Monckton.

The remaining features of this new scheme to treat workmen's compensation not as part of the law of employer's liability but as a social service may be briefly summarized as follows. The scheme will be comprehensive, will not provide for 'contracting out' schemes and will apply to accidents arising out of, and in the course of, employment and to specified industrial diseases. The liability, instead of being on the individual employer, will be placed upon a central fund out of which all benefits, both in disablement and fatal cases, and administrative charges will be paid. The fund will be maintained by weekly contributions from employers and workmen collected by stamp, with a contribution from the Exchequer. The weekly rates of contribution will be 6*d*. for adult men and 4*d*. for women, to be shared equally between the employer and workmen, with half these rates for juveniles. Benefits will not depend on a contribution qualification. The scheme will be under the general charge of the Minister of Social Insurance, with an advisory committee or council, on which employers and workmen will be equally represented, to advise the Minister on important matters of policy and administration referred to them. Employers and workmen will be equally represented on the local appeal tribunals.

The present procedure by which the workmen's claims against employers are subject to appeals to courts of law will be superseded by a system under which claims will be dealt with by a pensions-officer, subject to rights of appeal to local tribunals, and further rights of appeal to an industrial injury insurance commissioner whose decision will be final. In disablement cases the benefits will be at uniform flat rates. They will consist of an industrial injury allowance payable for an initial period while the workman is incapacitated for work, to be replaced, where the disablement is likely to be permanent or prolonged, by an industrial pension which will be supplemented by a special allowance if the pensioner is unemployable. Allowances will be given for family responsibilities, and treatment allowances and allowance for constant treatment in certain circumstances. No provision will be made for commutation of the pension by a lump sum payment, but where the injury results in only a minor degree of disability, provision will be made for a final settlement by an award of a gratuity or of a temporary allowance at a special rate with or without a final gratuity. In fatal cases the scheme provides for payment of a pension to the widow with an allowance for the first child, and a higher rate of allowance where the first child is an orphan. Provision will be made, in certain circumstances, for payment of a pension to one or both parents, or where no widow's or parent's pension is payable, to one adult dependent member of the deceased workman's family.

# PROBLEMS OF MODERN PHYSICS*†

By Prof. J. FRENKEL

## The Atomic Nuclei, Elementary Particles and the Nature of Matter

Nuclear physics emerged as a new independent science when, ten years ago, Cockcroft and Walton, working on a suggestion by Rutherford, first used protons artificially accelerated to immense velocities for bombarding other heavier atoms. Before that time, work of this kind had only been done with the help of radioactive substances, atoms of which are transmuted spontaneously without any outside agent, with the expulsion of alpha-particles (that is, helium nuclei) or beta-particles (fast electrons). These alpha- and beta-particles can be used to transmute artificially stable atomic nuclei. This method still has its value, and with its help (by bombarding beryllium with alpha-particles emitted in the natural radioactive disintegration of polonium) it was shown that besides protons (hydrogen nuclei) complex nuclei contain also neutrons. These are particles similar in mass to protons but having no electric charge. To obtain neutrons in the free state, nuclear physics has begun to use clusters of protons or deutons (nuclei of heavy hydrogen). These are accelerated to speeds corresponding to energies of some tens of millions of volts, by special apparatus such as the cyclotron, which was invented in the United States by E. O. Lawrence in 1930.

By such methods it has been possible to cause and study a large number of nuclear reactions of the type

$$A + B \rightarrow C + D,$$

where $A$ and $B$ are the initial nuclei and $C$ and $D$ the resulting ones. These 'alchemical' reactions are in many respects similar to ordinary chemical reactions; but they differ above all in the very much larger energy balance involved (as a matter of fact it is some million times larger). As a rule, one of the reacting particles ($A$ or $B$) is a very simple nucleus, such as a proton or deuton, or in the limiting case a helium nucleus, and the other is a complex nucleus. Thus the reaction $A + B \rightarrow C + D$ is usually treated as the artificial disintegration of the nucleus $A$ by the particle $B$ (a proton, for example), which leads to the expulsion from it of the particle $D$ (say a neutron). Really this reaction results in the union of $A$ and $B$ into a complex nucleus ($AB$), which is in an unstable, excited state, and so spontaneously splits up: $AB \rightarrow C + D$.

Like chemical reactions, these transformations can be either endothermic or exothermic. If $A$ and $B$ have a charge of the same sign, the stage $A + B \rightarrow AB$ requires a definite amount of energy for its initiation, and this is supplied by the kinetic energy of the bombarding particle $B$. This energy is needed to overcome the coulomb repulsion between the two particles. It is as if the nucleus $A$ were surrounded by a protective rampart in the form of a 'potential barrier' of tens of millions of volts, and if the motion of material particles were governed by the classical laws of mechanics then the particle $B$ would have to have kinetic energy at least as great as the height of this potential barrier in order to get past it. In

* Translated by E. R. Holmberg from *Vestnik Acad. Sci., U.S.S.R.*, 4–5 (1943), made available by courtesy of the Science Section of the Society for Cultural Relations with the U.S.S.R.

† Continued from page 421.

actual fact, the penetration of $B$ into $A$ which leads to the formation of a complex nucleus $AB$ is possible when $B$ has appreciably lower energies than this. This is due to a peculiar quantum effect known as the 'tunnel-effect'. However, the probability of this 'tunnel-effect' falls off very rapidly as the kinetic energy of $B$ decreases. For example, if the height of the potential barrier around $A$ is ten million volts and $B$ has a kinetic energy of one million volts, then only one such collision out of about ten thousand will result in $A$ and $B$ uniting. (At very small separations the coulomb repulsion between the nuclei is swamped by a force of attraction of a different kind about which we shall speak later.) So in spite of the tunnel effect, the reaction $A + B \rightarrow AB$ is for practical purposes associated with a definite activation energy; that is to say, the reaction can only take place when $B$ has kinetic energy greater than a definite value.

This position is accentuated when a particle $B$ travels through a solid body composed of atoms of $A$, for $B$ interacts with the electrons surrounding the $A$ nuclei and is thus rapidly slowed down. Since both the nuclei $A$ and the particle $B$ are extremely small, $B$ does not as a rule collide with an $A$ nucleus during the time it has a sufficient energy for an effective collision. As a result, such nuclear reactions occur very rarely, and out of many millions of $B$ particles used to bombard the substance $A$, only one will produce the desired result. So in spite of the fact that in many isothermal nuclear reactions a huge amount of energy is given off per unit weight, the utilization of this source of internal atomic energy is impossible in practice because of the small numbers of the reacting particles. In answer to a question put to him on this subject by a newspaper correspondent four years ago, Einstein said, "It is exactly like throwing bricks at a raven—at night".

The developments of the last two or three years have, however, somewhat shaken this pessimistic point of view, and have once more prompted the hope that the problem of transmuting atoms on an industrial scale can be solved.

If for our bombarding particle $B$ we use an uncharged body, a neutron in fact, then the activation energy becomes zero (because the neutron is not repelled by the nucleus $A$ and can penetrate it with an arbitrarily small initial velocity); and what is more, the neutron does not interact with electrons, behaving among them just as it would in empty space. A free neutron moving through a material body must therefore eventually combine with a nucleus according to the formula $A + B \rightarrow AB$, and its efficiency is 100 per cent. Unfortunately, however, free neutrons are not encountered in Nature (and if they did exist we could not direct their motion). They can only be obtained by excitation of a nucleus by artificially accelerated charged particles, that is, with the help of the reaction $A + B \rightarrow C + D$ (where $B$ denotes a proton, deuton or alpha-particle, and $D$ a neutron) which, as we have just seen, is very inefficient.

In 1939 a new reaction was discovered which involves the division of a nucleus of uranium brought about by slow neutrons. The uranium nucleus is at the limit of stability (on account of its very high electric charge) and divides, under the influence of the shock imparted by the neutron, into two equal parts (rather like a liquid drop which has been highly charged), and these two parts separate with the colossal energy of about 200 million electron volts. From this reaction two or three neutrons are set free with sufficiently high energy to 'explode' other uranium nuclei. Thus the process can, in principle, become like an avalanche. To get this chain reaction, it is necessary first to separate from uranium, which is a mixture of three isotopes, the light isotope with atomic weight 235, which only makes up 0·5 per cent of the total. The trouble is that this light isotope is much more unstable than the ordinary 238 isotope, and tends to disintegrate before it can capture a neutron. This leads almost immediately to a rupture of the neutron 'chain'.

Before the beginning of the War, physicists of all countries were searching for a practical solution of the 'uranium problem', that is, to find a certain way of causing this chain reaction of uranium.

The solution of this problem would open to humanity a completely new technical perspective. It would provide a new source of energy, millions of times more abundant (for equal masses of fuel) than coal or petroleum, although not so widely distributed. There is no doubt that immediately the War has finished, the uranium problem will occupy a central place in experimental and technical physics.

In addition to this there will also be an intensification of the attack on the problem of obtaining charged particles, nuclei of hydrogen and helium, with much larger energies than have been hitherto achieved. In the United States, where at the present time there are eighteen powerful cyclotrons in operation, a gigantic new one was under construction at the beginning of the War, capable of producing charged particles with energies of 100 million volts.

At these energies the efficiency of the nuclear reactions (measured by the ratio of the number of neutrons liberated to the number of charged particles used to produce them) must increase to values many hundreds and perhaps thousands of times greater than those hitherto achieved. If this is so, then the reactions can be carried out on an industrial scale; and besides just utilizing the atomic energy, it may be possible to obtain by transmutation rare and costly elements from those widely distributed in Nature.

The rarest and most costly of all are the radioactive elements—radium, thorium, actinium and the radioactive products of their disintegration. By bombarding normal stable atoms with neutrons, it has been possible to obtain new unstable atoms—radioactive isotopes of practically any element. For this it is necessary to be able to produce a sufficient quantity of free neutrons.

The cyclotrons already in existence provide in a large measure the solution to this part of the problem. With their help it is easy to obtain artificial radioactive elements in quantities equivalent in the intensity of their beta- and gamma-radiation to tens of kilograms of radium. So it is obvious what great value these results have for medicine (some large American hospitals have their own powerful cyclotrons).

These artificial radio-elements have already been widely used as indicators in various physico-chemical and biological investigations (diffusion in solid bodies, assimilation of various substances in living organisms, etc.).

One of the current problems of modern nuclear physics is therefore to increase the efficiency of nuclear reactions by producing particles with energies of tens and hundreds of millions of volts.

The cyclotrons are capable of communicating very high energies to nuclei, but not to electrons. But bombarding nuclei with high-speed electrons with energies around ten million volts appears to be more

direct and effective than using protons, deutons, etc., for producing transmutations of atoms and artificial radio-elements. The first step in this direction has recently been taken, using relatively slow electrons. At the beginning of 1941, Kerst in the United States designed and constructed a simple piece of apparatus which produced a stream of electrons of practically any required energy. The application of these ultra-fast electrons and the ultra-hard gamma-rays they produce, to the transmutation of atoms, will be energetically studied by physicists of all countries as soon as the War ends.

Until now, we have considered the chief problems of nuclear physics from the experimental and engineering points of view. But there are no less alluring and important problems on the theoretical side, and their solution must lead to far-reaching changes in our conceptions of the nature of matter. These new problems arose some ten years ago when the neutron and positron were discovered, and although the respective discoveries of these two particles came independently of each other, they are from the theoretical point of view closely connected.

Until the discovery of the neutron, a complex nucleus was imagined as consisting of protons and electrons (the latter in smaller numbers to give the corresponding positive charge). The existence of electrons in the nucleus was proved, so it seemed, by the fact that the majority of radioactive elements emitted them in the form of beta-rays with an increase of one unit in the positive charge of the nucleus. From the other side, this theory led to a series of unsurmountable difficulties connected with the magnetic and other properties of the nucleus. All these difficulties were overcome when, after the discovery of the neutron, it was shown that it was possible that the nucleus contained no electrons but only protons and neutrons. This, however, raised new difficulties over the question of the production of the electrons which form the beta-rays. The final conclusion is that these beta-rays arise (in the same way as photons when light is emitted) on account of the instantaneous transformation of neutrons into positrons. This bold idea, now firmly established experimentally, was first advanced by D. D. Ivanenko.

From this, of course, it would be imagined that the neutron is not an elementary particle like a proton but something like an atom of hydrogen, consisting of a proton and an electron. This, however, conflicts with the fact, discovered by Joliot in 1934, that certain artificial radioactive nuclei (for example, the one formed by the fusion of aluminium with an alpha-particle) emit positive beta-rays consisting of positive electrons or positrons. Thus the proton can also be regarded as a complex particle made up of a neutron and a positron. Neither of these pictures Is true. Both the proton and the neutron are elementary particles in the sense that neither can be subdivided into still finer particles, although they can change one into another with the simultaneous appearance of an electron or positron. A very convincing argument, based on the law of conservation of energy and momentum, shows that during these transformations certain neutral particles like photons must appear. These have been named the 'neutrino' and 'anti-neutrino'. (In the opinion of some theoretical workers, a photon is equivalent to a pair of these particles.)

Now positrons were discovered by Anderson and Neddermeier completely independently of the neutron, during an investigation of cosmic rays and the influence of magnetic fields on their motion. It was found that a positron came into being with an electron and disappeared in company with another. The energy necessary for the formation of such an electron-positron pair is obtained through the annihilation of a photon; conversely, when a positron-electron pair disappears, one or two photons appear and carry off the energy.

These results, which have been confirmed many times during the past eight years by experiment (it has been found possible to use ordinary gamma-rays and X-rays instead of cosmic rays), have thrown up new fundamental problems for theoretical physics—problems about elementary particles.

In the nineteenth century, the elementary particles appeared to be the atoms. 'Matter', which made up material bodies, was regarded as a collection of immutable atoms of 92 different kinds.

At the beginning of the twentieth century, it was shown that the elementary particles were smaller than atoms, and that the properties of the various kinds of atom were due to the envelope of electrons. The next to be studied was the atomic nucleus, the simplest representative of which is the hydrogen nucleus. It appeared that physics had come to the end of the process of the analysis of matter, having shown that all material particles consisted of protons and electrons, and that all physical and chemical forces (apart from gravity) could be traced to electric forces.

From 1932 onwards, that is, from the moment the neutron was discovered, this simple but incorrect picture underwent enormous conplication. Besides electrons there were positrons, and these and other particles did not appear to be immutable and indestructible but apparently could appear and disappear like quanta of light or photons. If the electrons in the atoms and material bodies appear indestructible, this is only because under normal conditions there are no positrons with which they can unite and so disappear, and also because, generally speaking, changes of protons into neutrons in the nucleus are energetically 'unprofitable' and therefore impossible.

The question arises, Is the indestructibility of protons and neutrons, apart from their mutual interchange, real or only apparent, like that of the electron? A number of demonstrations and experimental facts relating to the behaviour of neutrons and protons tends to show that they are in fact, in every respect except their mass, very similar to electrons. Therefore it seems very probable that, like electrons, they can in favourable circumstances appear and disappear in conjunction with their hypothetical opposites, the antiproton (that is, a proton with negative charge) and the anti-neutron.

If for the birth of an electron-positron pair we need the 'blow' of a particle (say, a photon) with an energy of one million volts, according to Einstein's law (product of mass and the square of the velocity of light) we need for the joint birth of a neutron or proton with its corresponding anti-particle a particle with an energy 2,000 times greater, that is, with an energy of $2 \times 10^9$ volts. At the present time, such particles are found only in the cosmic rays; so it is here that we must look for the phenomenon of the 'materialization' of neutrons and protons. Later on, when physics can produce artificially particles with energies around $10^9$ volts, the process of creating neutrons and protons (together with their opposites) will be controlled just as to-day we can control the creation of electron-positron pairs (by using hard

X-rays). The demonstration and control of these phenomena are the most interesting problems of nuclear physics. Of course, the reality may turn out much more complicated than our scheme based on analogies with proton and neutron on one side and with electrons on the other. The method of analogy is usually limited, but even so it is usually very fruitful (as was shown, for example, in the development of the study of light and matter). It is quite possible, however, that besides neutrons, protons and their antilogues, we shall be able to create particles with mass, magnetic moment and other properties hitherto unknown.

Physics had scarcely recovered from the unexpected appearance of neutrons and positrons when in 1937 Anderson discovered a new type of elementary particle, called the mesotron or meson, in cosmic rays. These particles have the same electric charge as an electron or positron, but their mass is some 200 times greater than that of an electron, that is, about one tenth that of the mass of a neutron or proton. They come into being in the upper layers of the atmosphere as the result of some as yet unknown process of interaction between the primary constituents of cosmic rays (photons, electrons or protons) and atomic nuclei. Their life is only some millionths of a second, yet in this time they are able to pierce the surface of the earth and penetrate to a depth of some hundreds of metres. Finally, the mesons are destroyed by some form of radioactive disintegration into electrons and neutrons.

Apparently the mesons play an essential part in the creation of attractive forces between protons and neutrons at small distances (as, for example, when they are bound together in a complex nucleus). According to a theory put forward in 1936 (that is, before the discovery of the meson) by the Japanese physicist Yukawa, the attraction between neutron and proton can be described as due to a kind of 'ball game' during which fragments are emitted by one particle and absorbed by the other. From considerations of the radius of action of nuclear forces, Yukawa concluded that these fragments should be about 200 times more massive than an electron, and would therefore correspond to mesons. However, the development of Yukawa's theory into a general explanation of nuclear forces has not been completely satisfactory as yet.

The development of physics during the last ten years has given rise to numerous completely new and unexpected problems connected with the nature of matter. The conception that matter consisted of indestructible elementary particles with immutable properties has been shown to be false. True, we have not yet had direct experimental demonstration of the destruction of the heavier elementary particles such as protons and neutrons, but already the one fact of their mutual interchange (in the beta-decay process of radioactive substances) shows that they are no more permanent than electrons. To-day, the problem of matter is concerned not so much with the explanation of the properties of elementary particles as with the explanation of the circumstances of their appearance, disappearance and mutual interchange. There is also the fact that certain particles are not only material objects but also agents of transmission of force between other particles. Thus, for example, photons play the part of transmitters of electro-magnetic forces between charged particles (electrons, protons and mesons), and are tossed across the separating space like balls. As we have seen above, mesons play an analogous part in the transmission of non-electromagnetic 'nuclear' forces between nucleons, as protons and neutrons are called. It is possible that nucleons themselves will be shown to be agents of transmission for as yet unknown forces between unknown particles.

The material world, which a short time ago contained only protons and electrons, is beginning to be occupied by an increasing number of particles of ephemeral existence and the double role of sources and transmitters of force. It is not too much to think that with the use of more powerful sources of energy, physics will be able, starting with known particles such as protons and electrons, to discover or rather create new particles with completely different masses, mechanical and magnetic moments, and electric charges. Some of these will be unstable or radioactive like the meson, while others, like the positron, will be stable in the absence of their anti-particle with which they unite and disappear.

This picture of matter, painted by modern physics, appears fantastic at first sight. Actually it is only unusual in terrestrial conditions. In the interior of stars where temperatures reach millions of degrees centigrade, the picture would be completely normal. To-day it can be taken as established that the source of energy coming from the sun and other stars is a nuclear reaction (probably chiefly the formation of helium from hydrogen). A still more intense stream of energy comes from certain stars during a spontaneous process of explosion, which results in the formation of what is called 'nova'. The metamorphosis of matter which occurs in the interior of these stars leads to the emission of a huge quantity of energy.

Information about these distant cosmic processes comes not only from the rays of visible light emitted by stars, but also from the cosmic rays which traverse the earth's atmosphere and penetrate the earth itself to a depth of some hundreds of metres. At the limit of the earth's atmosphere and in the stratosphere, the cosmic rays consist predominantly of photons and charged particles, electrons, mesons and some protons with energies ranging up to $10^{16}$ volts. The mesons, as also apparently the electrons, arise at the edge of the earth's atmosphere. So the question of the original composition of the cosmic rays remains unanswered, like the question of the origin of these rays. Providing the answers is one of the current problems of modern physics and astrophysics.

The conception that matter consists of elementary particles is one-sided, although practically it is justified under terrestrial conditions with our comparatively meagre sources of energy.

The mutual interaction of material particles can be handled with the help of the concept of the dynamic field. To-day we know three kinds of such fields: gravitational, electromagnetic, and finally the recently discovered and as yet unnamed fields which characterize nuclear forces.

These fields extend continuously throughout all space, concentrating in the neighbourhood of material bodies and particles which give rise to them.

The fields due to separate particles can be combined into a 'resultant'. This raises the question of the action upon an individual particle of its own field, which was first posed by J. J. Thomson in connexion with charged particles. It was shown that to a first approximation the reaction of an electromagnetic field upon the particle producing it was formally identical with the force of inertia. Applying this result to a single electron, Lorentz showed that

the inertia or mass of the electron could be completely attributed to the reaction of its electric field, if the charge was supposed as concentrated in a sphere of radius $10^{-13}$ cm. According to this, the law of motion of an electron turns out to be equivalent to the statement that the electron moves so that the total force on it, as determined by the resultant field, is zero. This 'Lorentz principle' is equivalent to the conservation of energy, momentum and moment of momentum for any system of electrons if we associate these magnitudes not with the electrons themselves but with the electromagnetic fields they produce.

That the concepts of conservation of energy, momentum, and moment of momentum, which arose in the mechanics of moving particles, could be applied to the electromagnetic field, had been realized before Lorentz put forward his theory. It was, however, only after the inertia of the electron had been explained as the result of electromagnetic reaction that its kinetic and potential energy could be treated as the electric and magnetic energy of its field.

In this way the electromagnetic field was shown to be the vehicle of all the mechanical properties (energy, mass, momentum, etc.) which were earlier ascribed to material particles. The particles were thus considered not as sources of fields but as products of them—rather like knots in the lines of force. The question of the force of interaction between these 'knots', like the question of self-reaction, loses its meaning, as the resultant force experienced by each of them is zero. The laws of motion of the particles formed by the field agree completely with the law of conservation of energy and momentum of the field.

The further development of field theory concerns the solution of three types of problems: first, problems of the structure of electrons and the atomic nature of electric charge; secondly, the dynamics of nuclear fields; and thirdly, the quantization of dynamical fields.

The structure of the electron has been tackled hitherto from two angles, one treating it as a point charge and the other as if it had extension. Along both avenues of approach insuperable difficulties have been encountered. These difficulties, as also those connected with the atomic nature of the charge, will probably be solved by a thorough application of quantum theory ideas, but before this is possible we need further development of modern quantum mechanics.

The importance of the dynamics of nuclear fields is due to our ascribing the inertia of nuclear particles to the reaction of their own fields. The attempts which were made earlier to treat the inertia of protons as due to the reaction of their electromagnetic field lost their meaning when the neutron was discovered, for the neutron, even without electric charge, has a mass very close to that of the proton. In a number of papers to-day this non-electromagnetic mass is treated as a magnitude corresponding to some nuclear 'charge' bearing the same relation to the nuclear fields as the electric charge does to the electromagnetic field. The protons and neutrons themselves are thus regarded as 'knots' in a nuclear field, either apart from or in combination with an electromagnetic field.

From this point of view matter is a collection of interpenetrating dynamical fields, electromagnetic and nuclear, with material particles and bodies forming knot points. These points can under certain conditions appear and disappear, although the energy of the field, the momentum and other fundamental properties remain unchanged.

This picture is still only a provisional sketch. In order to complete it we need further development of the ideas of the quantum theory. The essence of this theory is an organic statistical synthesis of continuity and discontinuity. It was first introduced in the studies of the motion of particles and of light, and through the development of the quantum aspect of dynamical fields has helped enormously towards the solution of the problem of matter. As a result, new particles have appeared on the physics scene. These are in addition to those which create, or are created by, the known dynamic fields, and serve as vehicles of interaction between the original particles.

In the case of electromagnetic fields, for example, the sources, or if you like products, of which are electrons, the corresponding quantum particle, the transmitter of electromagnetic action is the photon. In the case of nuclear fields created by protons and neutrons, the corresponding quantum particle is apparently the meson. On the other hand, mesons, like electrons, take part in the creation of the electromagnetic field. This prompts the very natural thought that in a sense all particles are quanta with respect to some other particles. In particular, the electron positron pair could in all probability be treated as quanta of some as yet unknown field, which in its turn is created by other particles, for example, the nucleons. But the nucleons could play the same part in relation to other particles probably as yet undiscovered.

But here we are crossing the boundaries of modern physical science and risk falling into the realm of unscientific phantasy. Nevertheless, recent developments of physics have shown how limited and narrow our previous ideas about the physical world were, so in a survey of the problems of modern physics we need not fear a certain extension of its frontiers, even if it is not yet fully justified.

# VALUE TO THE STUDY OF CHINESE CIVILIZATION OF COLLECTIONS AND MUSEUMS IN BRITAIN

By PROF. W. PERCEVAL YETTS, C.B.E.

Professor of Chinese Art and Archæology in the University of London

"AT no period in the history of the world has the attention of civilized nations been so fully directed towards China, its early history and modern position as at the present moment." These words, though true to-day, were in fact written exactly a century ago to preface the catalogue of London's first Chinese Exhibition. It was the enterprise of an American, named Nathan Dunn, who, during twelve years spent in China as a merchant, had collected the 1,341 exhibits, representing, so he claimed, "the Chinese world in miniature". More than fifty thousand persons visited his collection in a pavilion built for it near Hyde Park Corner. Presumably the exhibits were in due course shipped back to their owner in Philadelphia.

The next display of the kind remained in England and so contributed to the beginnings of our Chinese

collections. At the wish of the Prince of Wales, a special invitation to take part in the International Fisheries Exhibition of 1883 had been sent to the Chinese Government, which responded by instructing the Inspectorate-General of Maritime Customs to make the necessary arrangements. The resultant Chinese Court in the Exhibition at South Kensington was a great success, and it continued with additions to do service at two other International Exhibitions, Health and Inventions, held in 1884 and 1885 respectively.

The catalogue of the Chinese part at the Health Exhibition shows that the intention was, like that of Mr. Dunn, to represent the material civilization of everyday China. There were typical living-rooms fully furnished, lay figures dressed in costumes worn by every class, various means of transport including a catafalque, stoves, weapons and a macabre item in an effigy of a dead Buddhist priest undergoing cremation. Thirty Chinese came from China: ten shopkeepers to ply their trade in four well-stocked shops; ten cooks to supply Chinese dishes in the restaurant; six musicians to sing, play and act; a carpenter, a painter and two barbers to exercise their callings in public. As to the shops, the carved fronts for which came from China, one was occupied by a Peking firm of curio dealers, one by a firm from Kiukiang with modern porcelain, one by tobacconists from Hankow, and one by a Canton firm selling miscellaneous fancy goods.

These exhibitions marked a new phase. Since the sixteenth century, when free intercourse by sea began between the Far East and the West, products of Chinese craftsmanship had been imported in profusion. Few houses of the well-to-do in Britain lacked some example, and the strange charm of these things inclined our forefathers to accept unhesitatingly fanciful and Utopian accounts of their place of origin. Indiscriminate admiration for Chinese notions and products, and those supposedly Chinese, was the vogue. Towards the latter part of the eighteenth century fashion changed and intellectual Europe became obsessed with the world of ancient Greece and Rome. In the nineteenth century commerce and other contacts increased our opportunities of knowing the real China, and then we started to explore the field of art and archæology in earnest. The notable collection of Mr. A. W. Franks (afterwards Sir Wollaston Franks), first exhibited in 1876, passed in time to the British Museum and provided the foundation of Chinese ceramic collections there. The exhibition in 1876 was ably described by Mr. Franks in a remarkable catalogue which shows a true scientific spirit. But the greatest advance in such studies was achieved by the numerous writings of Dr. S. W. Bushell, who had the advantage of contact with Chinese scholars while serving as medical officer to the British Legation in Peking during 1868–1899. He it was in 1882 who made a basic contribution to the Victoria and Albert Museum by undertaking to buy for it a number of objects of Chinese craftsmanship, chiefly porcelain. For the same Museum he wrote two volumes of a handbook on "Chinese Art", published in 1904 and 1906, which as to scope and scholarship was a pioneer work and has not yet been bettered in some respects. Another medical man did a like service as to Chinese painting. William Anderson, who had been professor of anatomy and surgery at a college in Tokyo, sold his collection of paintings to the British Museum in 1882. Of these, 114 were Chinese, and they formed a nucleus. Four years later was published his catalogue of Chinese and Japanese paintings in the Museum, the first serious study of the subject in a Western language—again an instance of British initiative.

Such were the signs during the middle nineteenth century of reawakened interest in the material culture of China. In both our great national museums progress was quickened by bequests and the example of private collectors. For example, George Salting allowed for more than twenty years his unrivalled collection of some two thousand pieces of Ch'ing porcelain to be displayed in the Victoria and Albert Museum, and bequeathed it to remain there after his death, which occurred in 1910. Our greatest collector was George Eumorfopoulos. During the first thirty-five years of this century he gathered together with rare enterprise and acumen more than four thousand objects representative of nearly all media of Chinese art and craftsmanship. His collection set a new standard; it was bought for the nation in 1935 and then divided between the British and the Victoria and Albert Museums.

Mention has not yet been made of bronzes, because they scarcely figured at all in the early days. Probably Eumorfopoulos was the first to recognize the significance of ritual bronzes as the chief monuments of ancient Chinese civilization and basic criteria for the beginnings of Chinese art. Even Bushell seems to have been unacquainted with the best archaic bronzes, if one may judge from his writings. Though Eumorfopoulos gradually added many to his collection, no truly representative lot of bronzes had been seen in Great Britain until the great International Exhibition of Chinese Art in London, which during less than four months in 1935–36 attracted nearly half a million visitors. Many considered the bronzes the most illuminating exhibit because of the carefully chosen series of 108 pieces lent by the Chinese Government. Undoubtedly this display, so essential to an understanding of early Chinese culture, created a deep impression and stirred collectors to fresh effort. Quite a number now own notable bronzes: for example, Sir Alan Barlow, Mr. Robert Bruce, Mr. A. E. K. Cull, Sir Herbert Ingram, Sir Neill Malcolm, Mr. H. Oppenheim and Mr. and Mrs. Walter Sedgwick. The Cull Collection, small yet important, may be studied in a published catalogue.

From the first the ceramics have been better represented than any other medium. An attempt at a statistical survey would be wearisome; suffice it to say that almost all museums in Britain have some specimens, but comprehensiveness is approached in none except the British and the Victoria and Albert. The Lady Lever Art Gallery at Port Sunlight has a magnificent range of Ch'ing porcelain and little from other periods. That reflects the prevailing aim of collectors in the last century, who were content with these superb later products. During recent decades the fashion has been to seek the wares of earlier periods, and some remarkable collections are the outcome. Those of Sir Alan Barlow, Mr. and Mrs. Alfred Clark, Sir Percival David and Sir Herbert Ingram should be mentioned. The Clark Collection may be studied from photographs at the Courtauld Institute of Art, and an account of the David Collection has been published. The Ingram Collection is specially strong in Yüeh ware.

In a short article omissions are inevitable. Yet jade must not be left out, since it has always figured prominently in the social and religious life of China. That ardent connoisseur, the late Oscar Raphael,

had a special liking for jade. His fine collection of Chinese antiquities in jade and other media was bequeathed to the British and Fitzwilliam Museums. Numerous jade carvings are among Sir Charles Hardinge's collection of 2,539 small objects made of more than a hundred different materials, the whole affording striking evidence as to Chinese beliefs, customs and handicrafts. Also of ethnological value is the Chinese section in the Wellcome Historical Medical Museum. It contains, besides drugs and acupuncture instruments, very diverse exhibits, including many amulets. The student will find special satisfaction in the Cambridge University Museum of Archæology and Ethnology, because here are weapons, tools, currency and pottery from the earliest times, all arranged in chronological sequence. Finally, a word is due concerning the inscribed bone and tortoise-shell fragments found near An-yang at the end of last century. They put back the limits of authentic history and tell us of Chinese civilization more than three thousand years ago. In all, some 2,820 of these fragments belong to three collections: in the Royal Scottish and British Museums and in the ownership of Mr. L. C. Hopkins, *doyen* of the few Western students of archaic Chinese script.

To sum up: there are public and private collections in Britain rich in objects with æsthetic appeal, but poor in those not classed as 'art' which throw equal light on the history of Chinese civilization. Except in the aforesaid Cambridge Museum, small effort seems to have been made to trace evolutionary sequence in the ordinary things of life. Our collections are much scattered and duplicated; we need a central Chinese Museum.

# NEWS and VIEWS

## Visit of Indian Men of Science

IT is now expected that the distinguished Indian scientific men who will shortly visit Great Britain will arrive about the second week of October. They expect to stay in England for about seven weeks, during which time they will visit important scientific laboratories and industrial, medical and agricultural research institutions in and near London in the Midlands and north of England and elsewhere in the United Kingdom; they will also discuss modern scientific progress with such bodies as the Royal Society, the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council and the Radio Board. This visit is a sequel to the visit to India last winter of Prof. A. V. Hill, secretary of the Royal Society. It was then suggested that Indian scientific men should be given an opportunity of coming to the United Kingdom and of establishing closer relations between the many new scientific organizations in India and corresponding organizations here. The proposal was warmly welcomed by H.M. Government and by the Government of India. They will be the guests of His Majesty's Government while they are in Great Britain.

The party will probably consist of the following: Dr. Nazir Ahmad, director of the Cotton Technological Laboratory, Matunga, Bombay; Colonel S. L. Bhatia, deputy director-general of the Indian Medical Service; Sir Shanti S. Bhatnagar, director of scientific and industrial research, India; Sir Jnan Chandra Ghosh, director of the Indian Institute of Science, Bangalore, and president of the National Institute of Sciences of India; Prof. S. K. Mitra, of the University College of Science, Calcutta, chairman of the Radio Committee of the Board of Scientific and Industrial Research; Prof. J. N. Mukherjee, professor of chemistry, University of Calcutta; Prof. Megh Nad Saha, of the University College of Science, Calcutta. Colonel Bhatia's departure from India is expected to be delayed, and he will not join the party until later.

## Professorship of Concrete Technology at the Imperial College, London

A RECENT benefaction from the Cement Makers' Federation has enabled the Imperial College, with the approval of the University of London, to institute in its City and Guilds College a new chair of concrete technology. It may not be possible to appoint a professor until after the termination of war with Germany. The chair will be instituted in the first instance for ten years, and will be attached to the existing Department of Civil Engineering. The duties of the professor will be to provide advanced instruction in the principles and technological application of reinforced concrete, to conduct research in his subject, and to consult with industry regarding the practical experience which it will give to students in training. In order to establish the necessary contact with industry, an advisory committee is contemplated, with appropriate representation of interested bodies, which will report to the governing body of the College. At the end of the ten-year period it will review the working of the scheme and advise as to its continuation or termination. A noteworthy feature of the scheme, which might well be followed as a model in future planning of training for technology, is an arrangement, sponsored by a number of building and civil engineering contractors, whereby bursaries will be made available to students devoting one or two years (after a preliminary study of the basic sciences) to intensive study of concrete technology. It has been agreed that industry looks for graduates broadly trained in the fundamental sciences, but with specialized knowledge superimposed; and that its willingness to provide such bursaries is the best assurance that can be given of its intention to absorb men who have thus committed themselves to a specialized course of training.

## Prof. Frank Allen

Prof. Frank Allen has just retired from the position of head of the Department of Physics, of the University of Manitoba, Winnipeg, Canada, after forty years of service. He is a native of Canterbury, New Brunswick, born on February 6, 1874, and is thus one of the great army of educationists given by the Maritime Provinces of Canada to the West. After graduation from the provincial University of New Brunswick in 1900, he spent four years at Cornell, at a time when the United States physicists were just beginning to realize the importance of their calling. Allen received his Ph.D. degree at Cornell and in the autumn of 1904 entered on his work in Manitoba. He has made an important contribution to physics in Canada. He was elected a fellow of the Royal Society of Canada in 1909 and served as a member of the National

Research Council of Canada from May 1932 until March 1937.

Of his work at Manitoba, Mr. Sidney Smith, who has just retired from the post of president of the University of Manitoba, says: "Dr. Frank Allen was a pioneer and a builder in the first university in Western Canada—the University of Manitoba. Appointed to the staff of that University in 1904, when it became a teaching institution, he founded the Department of Physics, of which for forty years he has been the distinguished head. As a gifted teacher, his record may be read in the careers of generations of students. To the new university he brought an inquiring mind and the spirit of research. He constantly advocated that a university is charged with the responsibility of conserving and transmitting the wisdom and culture of the past and also with the duty of extending the horizons of knowledge. He always considered physics in relation to the other physical sciences and, in fact, as a part of a truly liberal education. Specialization did not narrow his outlook: it broadened his interests and influence".

Prof. Allen's research work has been almost entirely on the rather dim borderland where physics, physiology and psychology, the 'three p's', meet. His first work was on colour vision. His aim was to investigate the nervous actions underlying colour vision and other sensory activities. In his own words, the aim of his work was first to place the sense of colour vision on a foundation of experimentally ascertained physiological principles, and then to establish the fundamental identity of the processes underlying all of the special senses, including vision, hearing, taste and touch. Prof. Allen is now engaged on collecting the results of his life-work; many of his papers have appeared in scientific journals, particularly the *Transactions of the Royal Society of Canada*. Prof. Allen's wife died some years ago, but he has a family of two sons and one daughter—Dr. J. F. Allen, who has just been elected to a fellowship at St. John's College, Cambridge; William Allen, an architect in London (England); and Miss Lillian Allen, on the staff of the University of Manitoba. Prof. Allen's many friends join in wishing him many happy years of useful work.

## Chair of Psychology, Birkbeck College

DR. C. A. MACE, who has been appointed to the chair of psychology at Birkbeck College, University of London, holds the degrees of M.A. Cambridge and D.Litt. London. After leaving Cambridge he was for a time at University College, Nottingham. From there he was appointed lecturer in logic and psychology in the University of St. Andrews. He left Scotland to take up the position of University reader in psychology at Bedford College, London. Dr. Mace has published books and papers in both psychology and philosophy, his best-known work in philosophy being the "Principles of Logic" (1933). In psychology his interests are mainly in social and industrial spheres, and in problems concerning economical methods in learning. In 1935 he published a monograph "Incentives, some Experimental Studies" (Ind. Health Res. Bd. Report No. 72). This was mainly concerned with problems arising in industry owing to variations in the will to work of the employee in contrast to the more usual studies of ability. Dr. Mace has also worked on the fluctuations of interests of college and Workers' Educational Association students over several years, and on the psychological make-up of groups of friends. His latest publication is a paper in the *Sociological Review* on some of the psychological causes of national prejudice. In this paper he makes an important theoretical distinction between stereotypes, or rigid mechanisms of thought, and plastotypes, or more fluid ones. Dr. Mace has always been keenly interested in adult education, so his appointment to Birkbeck College seems a singularly happy choice.

## Book Production

IN connexion with the recent discussion of the shortage of educational and other books (see *Nature*, September 9, p. 319), the following reply given by Mr. Dalton in the House of Commons on September 26 should be noted: "The Minister of Production has agreed, at my request, to increase the allocation of paper to publishers of books as from the end of next month to 42½ per cent of their pre-war usage. I hope that the publishers will do all they can to devote this extra paper to supplying liberated territories, as well as Empire and other oversea markets. The Minister of Production has also increased by more than one third the allocation to my special reserve, and has made a further additional allocation for certain classes of educational books. I am in touch with the Minister of Labour about the supply of labour for printing and binding." The additional allowance of 2½ per cent of publishers' 1938–39 consumption of paper will be welcome; but it is difficult to see how Mr. Dalton's hope that the extra paper should be used to supply liberated territories and overseas markets could be fulfilled. It seems very doubtful if any publisher would be able to differentiate sharply between books for such overseas markets and those for use in Great Britain. In any event, there is a definite shortage of educational and scientific books, which are needed as much at home as abroad. Publishers are well aware of this, and will no doubt do all in their power to overcome it. They will also note Mr. Dalton's remark that he is in touch with the Minister of Labour about the supply of labour in the printing and binding trades. As we have said before, these trades have been stripped of labour, and until more workpeople are made available, full use cannot be made of the additional allocation of paper for the production of educational and other books.

## Practical Limits in Social Reform

BULLETIN No. 5 of the Tory Reform Committee "What Shall We Use for Money ?" is of interest as an attempt to indicate the broad limits of what is politically and economically practicable in the field of social reform. The pamphlet distinguishes between income and outlay of the nation as a whole, and the Exchequer aspect, or that part of the national income which passes through the Revenue and Expenditure of the Exchequer. These aspects are discussed separately, and a survey of post-war national outlay and national income after the War emphasizes that our standard of living will, and always must be, dependent on the maintenance of high productive efficiency. Discussing, in conclusion, finance and politics, the Tory Reform Committee does not believe that the measures of social reform which it has championed are beyond the taxable or economic capacity of the nation to bear, or beyond the willingness of the majority of individuals to provide by personal effort and sacrifice. It is well aware, however, that such

limits exist, and they have for the time being been nearly approached; the Committee urges that the time has come to concentrate upon increasing the national income in the cause of social progress by every means and particularly by increased industrial efficiency. The pamphlet is an honest attempt at clear thinking and is a striking contrast to recent pronouncements regarding the adoption of a forty-hour week, which have omitted all indication of the price which has to be paid for adopting any such objective in our immediate post-war programme.

## Geographical Research in China

AN account of geographic research in China by Prof. Chi-Yun Chang (*Ann. Assoc. Amer. Geog.*, **39**, No. 1, March 1944) contains a record of a great deal of valuable work, much of which, under present conditions, may have escaped notice in Great Britain. Large numbers of topographical maps have been printed recently including a bathyorographical one of the whole of China on a scale of one to three million. A beginning of land utilization maps has been made, and a generalized soil map has been published. The Research Institute of Meteorology of the Chinese Academy has been investigating the problems of winds and rainfall over China with the result that the old conception of the south-east monsoon being chiefly responsible for the rainfall has been displaced in favour of cyclonic influences being mainly responsible: most of the rainfall appears to be associated with cold fronts. In historical and other aspects of human geography research has also been active. The report also notes the development of geographical education, probably temporarily interrupted, the foundation of the Chinese Institute of Geography and a number of geographical periodicals.

## Russian Papers on Pure and Applied Mathematics

A NUMBER of Russian publications containing papers on pure and applied mathematics have been received, and most of them have at least an abstract in English, French, or German. In a few cases the papers are entirely in English. They include numbers of the *Bulletin of the U.S.S.R. Academy of Sciences (Mathematical Series)* (1941–43), the Moscow *Receuil Mathématique* (1942–3), *Applied Mathematics and Mechanics* (1943), *Engineering Review* (1943), and *Comptes Rendus* (1943). It is difficult to describe the mathematical contributions in a limited space; they deal with trigonometrical series, the theory of functions and other topics such as are treated in our own mathematical journals. As regards the engineering papers, attention may be directed particularly to the papers by Glagolev, Popov and Proktor on "The Mechanical Properties of Rubber"; Erokhin, Nikolaeva and Oghibalov on "Dynamic Brittleness of Metals"; Kasparov on "Distribution of Pressure on the Blades of a Hydroturbine" (all in *Eng. Rev.*, **2**; 1943) and to those by Astrov, Levin, Pavlov, and Khristianovitch on "The Design of the Laval Nozzles", Pugachev on "The General Problem of Exterior Ballistics for Aviation Bombs", Četajev on "The Sufficient Conditions of the Stability of a Rotating Motion of a Projectile", Banin on "Approximate Conformal Transformations applied to the Plane-Parallel Flow past an Arbitrary Shape" (all in *App. Math. and Mech.*, **7**; 1943).

## Identification of Timbers

MR. ALEXANDER L. HOWARD'S "Studies of the Identification of Timbers" was reviewed in *Nature* of November 7, 1942. It is interesting now to record the appearance of a supplement containing 153 photomicrographs of different kinds of wood ("Supplement to Studies of the Identification of Timbers." By Alexander L. Howard. Pp. 19. London: Macmillan and Co., Ltd., 1943. 5*s*. net), and one cannot but admire the author's continued enterprise in producing a supplement to a book of this kind in time of war, and promising yet another in the near future. Attention was directed, when reviewing the original volume, to certain features of the book which limit its practical value. Since the supplement has been prepared along precisely the same lines, it will be found to present similar difficulties when used for the practical identification of timbers.

## Announcements

WE regret to announce the death of Sir John Ledingham, C.M.G., F.R.S., formerly director of the Lister Institute, London, on October 4, aged sixty-nine.

THE Council of the Royal Aeronautical Society has awarded the Society's Gold Medal to Air Commodore Frank Whittle, for his work on jet propulsion. This award is the highest the Council can make, and has been made on only seven previous occasions, the recipients being as follows: Wright Brothers (1909), Prof. O. Chanute (1910), Prof. G. H. Bryan and Mr. E. T. Busk (1915), Dr. F. W. Lanchester (1926), Prof. L. Prandtl (1927), Sir Richard Glazebrook (1933) and Senor Juan de la Cierva (posthumously, 1937).

THE following appointments have been made in the University of London: Mr. H. Berry, to be professor of pharmaceutics; Dr. W. H. Linnell, to be professor of pharmaceutical chemistry. Both appointments are tenable at the College of the Pharmaceutical Society.

THE National Council for Mental Health has arranged a course of ten lectures, by various authorities, on "The Psychology of Frustration and Fulfilment in Adult Life". The lectures, which are addressed specially to those with social and educational interests, are being given on Tuesdays at 5.30 p.m. at the Caxton Hall, London, S.W.1, and began on October 3. A parallel course is being given on Wednesdays at 5.30 p.m. at the Friends' Meeting House, Bull Street, Birmingham. Tickets for the course can be obtained, price £1, from the Secretary, National Council for Mental Hygiene, 39 Queen Anne Street, London, W.1, or single tickets, 3*s*. 6*d*., at the door before each lecture.

THE Selection Committee of the Harrison Memorial Fund, consisting of the presidents of the Chemical Society, the Royal Institute of Chemistry, the Society of Chemical Industry and the Pharmaceutical Society, will make an award of the Harrison Memorial Prize in December 1944. The Prize, not exceeding £150, is open to a chemist of either sex, being a natural born British subject and not at the time more than thirty years of age, for original investigations in chemistry carried out and published during the past five years. Further particulars can be obtained from the President, Chemical Society, Burlington House, Piccadilly, W.1. Applications must be received not later than December 1, 1944.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Extraction and Purification of Penicillin

Published methods for the extraction and purification of penicillin[1,2,3] are all based on the observation that penicillin can be extracted by ether, amyl acetate or chloroform from strongly acid aqueous solutions. Considerable losses of the antibacterial substance occur during these operations as penicillin is very rapidly destroyed in acid environment, particularly when shaken with air at room temperature.

A search was made for solvents which would extract penicillin from aqueous solutions at a *p*H not harmful to penicillin. It has been found that a large proportion of the antibacterial substance can be extracted by *n*-butyl alcohol from culture filtrates adjusted to *p*H 6·4, at which penicillin is most stable. When a suitable amount of ammonium sulphate was added to the culture filtrate, penicillin was then almost completely extracted by the butyl alcohol. The addition of ammonium sulphate was also of advantage as it precipitated the greater part of the inactive pigments. Penicillin was brought back into aqueous solution by the addition to the butyl alcohol extract of light petroleum ether and dilute sodium bicarbonate solution. During this procedure further purification of penicillin was effected as some impurities remained in the petroleum ether. The concentrated penicillin solution may be further purified by the usual method (ether extraction).

A typical experiment was as follows: 2,000 ml. of the crude culture fluid was adjusted with phosphoric acid to *p*H 6·4 and 800 gm. of ammonium sulphate was dissolved in it. A precipitate containing inactive proteins and pigments formed and was filtered off. 400 ml. of the filtrate was mixed with an equal volume of *n*-butyl alcohol and extracted by shaking. The same butyl alcohol extract was used for the subsequent extraction of four further 400 ml. portions of the culture fluid. To the strong butyl alcohol extract, 400 ml. in bulk, an equal volume of light petroleum ether was added. From this mixture penicillin was extracted by shaking into 200 ml. of a 2 per cent aqueous solution of sodium bicarbonate. The greater part of penicillin contained in the culture fluid was obtained in this way as an aqueous solution of the sodium salt of penicillin. The remaining penicillin was obtained by a second extraction of the butyl alcohol–petroleum ether mixture with another portion of the sodium bicarbonate solution.

The principal advantages of this method of extraction are: (1) there is no loss of penicillin during extraction as it is extracted at the *p*H point of its greatest stability; (2) the antibacterial substance is almost completely extracted from the culture fluid; and (3) considerable concentration and purification is achieved by the same process. Further advantages of the method are that extraction can be carried out at room temperature and that only relatively small quantities of solvents are required. The procedure is simpler and more efficient than other methods of purification and appears suitable for large-scale purification of penicillin.

I am much indebted to Prof. P. L. Sutherland for his advice and interest throughout the course of this investigation. My thanks are due to Mr. G. Denton for technical assistance.

## Thiophanone Derivatives

Following the recent papers of P. Karrer *et al.*[1,2,3,4] and the communications of E. R. Buchman and H. Cohen[5], R. B. Woodward and R. H. Eastman[6] and L. C. Cheney and J. R. Piening[7] on the synthesis of thiophanone derivatives, it seems desirable to direct attention to work carried out independently in this laboratory on the same subject.

Our method of preparing thiophanones is substantially the same as that of the above authors, and we have described it in the patent literature[8,9,10]. However, in our experiments on the ring closure of ethyl S-(β-carbethoxyethyl)-thioglycollate under the influence of powdered sodium in benzene, we found that ethyl thiophan-3-one-2-carboxylate always at least predominates, whereas Karrer *et al.*[1] and Buchman and Cohen[5] report the formation of the 4-carboxylate. Our evidence for this assertion is based on the following products obtained from the Dieckmann reaction on: (i) ethyl S-(β-carbethoxyethyl)-thioglycollate, giving a cyclic keto-ester which yielded a crystalline derivative with urea[11], m.pt. 173°; (ii) methyl S-(β-carbethoxyethyl)-thioglycollate, giving a product, with urea derivative, m.pt. 222°; (iii) ethyl S-(β-carbmethoxyethyl)-thioglycollate, giving a product, with urea derivative, m.pt. 173° (admixture with that from (i) showed no depression); and finally (iv) methyl S-(β-carbmethoxyethyl)-thioglycollate, the urea derivative of the product of which melted at 222° and did not depress the melting point of that from (ii) on mixing.

That mixtures do occur was shown by subjecting *n*-butyl S-(β-carbmethoxyethyl)-thioglycollate to the same conditions (namely, powdered sodium in benzene), when *two* products were obtained. The main fraction was *n*-butyl thiophan-3-one-2-carboxylate (found: C, 52·7; H, 7·2; S, 15·6. $C_9H_{14}O_3S$ requires C, 53·4; H, 6·9; S, 15·8 per cent) and gave a derivative with urea, m.pt. 170–172° (found: C, 48·8; H, 6·3; N, 10·7. $C_{10}H_{16}O_3N_2S$ requires C, 49·2; H, 6·6; N, 11·4 per cent). The small low-boiling fraction gave a urea derivative, m.pt. 245°, the analysis of which showed it to be derived from methyl thiophan-3-one-4-carboxylate (found: N, 13·2. $C_7H_{10}O_3N_2S$ requires N, 13·9 per cent).

Although it was possible to introduce a side chain in the 2-position (as would be required to reproduce the β-biotin carbon skeleton) by condensation of the corresponding halogeno-compound with ethyl thiophan-3-one-2-carboxylate in the presence of sodium ethylate[10], nevertheless this method was soon replaced by the more satisfactory one of subjecting esters of the type EtOOC.$CH_2$.$CH_2$.S.CH*R*.COOEt (in

which $R$ is the desired substituent) to the action of powdered sodium in benzene solution. In this case, of course, a non-ambiguous formation of the 4-carboxylate occurs. The product was treated with water at 200°[12] to yield directly the required 2-substituted thiophan-3-one[9].

It is worth recording that we synthesized the α-halogeno pimelic acid[13] required for the preparation of thiophan-3-one-2-valeric acid, by converting ethyl hydrogen pimelate to the corresponding acid chloride, which was brominated to the α-bromo-acid halide, followed by alcohol treatment to yield ethyl α-bromopimelate. We believe this constitutes a simpler process than that of Karrer *et al.*[4] or of Cheney and Piening[7].

Fuller details of this work will be published elsewhere.

## Peroxidase Activity of the Thyroid

THE finding of Schachner *et al.*[1] that the *in vitro* formation of diiodotyrosine and thyroxine by thyroid slices, with radioactive iodine, $^{131}I$, as indicator, is inhibited by cyanide, azide, sulphide and carbon monoxide (particularly in the dark) led to an investigation of the occurrence of oxidases in the thyroid. The production of a strong peroxidase reaction and the recent publication of a paper by Dempsey[2] focused attention on this enzyme. Dempsey, using the benzidine histological technique, reported the presence of peroxidase in the follicular cells of the thyroid. He claims that the peroxidase reaction is not due to hæmoglobin, since it was discrete and there was no continuity between erythrocytes and intracellular reacting granules. The cellular peroxidase reaction was found to be inhibited by thiouracil and in much smaller concentration than was necessary to inhibit the hæmoglobin reaction. Owing to the non-specificity of the benzidine reaction and the fact that the high concentration of hydrogen peroxide employed in the histological technique would effectively inhibit true peroxidase, however, this finding requires more careful investigation, because of the obvious implications of the reported inhibition by thiouracil.

Since peroxidase catalyses the liberation of iodine from inorganic iodides by hydrogen peroxide, its presence in the thyroid would serve a useful function. Lipmann[3] found that peroxidase is inhibited by sulphonamides. This, however, is contrary to the finding of Keilin and Mann[4], but these latter workers found peroxidase to be partially inhibited by sodium fluoride, another goitrogenic agent. Westerfeld and Lowe[5] discuss the possibility that the quinol-ether linkage in thyroxine may be formed through a peroxidase condensation. They found a quinol-ether among the oxidation products of *p*-cresol by peroxidase. Keston[6] suggests that the xanthine oxidase system may play a part in biological iodinations, furnishing peroxide essential for peroxidase activity. Employing radioactive iodine, $^{131}I$, and using milk as a source of xanthine oxidase, peroxidase and caseinogen, and adding xanthine as a substrate for the xanthine oxidase, he obtained significant iodination of the caseinogen. This reaction was inhibited by thiourea. Addition of catalase, however, did not affect the iodination.

The existence of peroxidase in animal tissues has been doubted. Bancroft and Elliott[7], however, consider that both spleen and lung probably contain true peroxidases, and Huszak[8] has made the interesting observation that the suprarenal medulla contains an active peroxidase but lacks a cytochrome oxidase system. The demonstration by Altchul, Abrams and Hogness[9] of a peroxidase, 'cytochrome c peroxidase', specific for cytochrome *c* suggests a wider distribution of peroxidase than is usually supposed and also a more important role for hydrogen peroxide in biological oxidations.

In the following experiments, horse thyroids were used, obtained very soon after death, each thyroid weighing approximately 10 gm. In the preliminary experiments, filtered aqueous extracts of very finely minced and ground tissue were used, the thyroid being extracted with five times its weight of water containing chloroform. Such extracts gave a strong peroxidase reaction (*p*-phenylene diamine, benzidine and pyrogallol as substrates) and a catalase reaction.

Peroxidase was determined by the purpurogallin method of Willstäter and Stoll[10] as modified by Elliott and Keilin[11]. This was inhibited to a certain extent by both thiourea and thiouracil as shown in Table 1. The catalase activity was not affected.

TABLE 1. INHIBITION OF HORSE THYROID 'PEROXIDASE' ACTIVITY BY THIOUREA AND THIOURACIL

| Concentration of drug | Percentage inhibition produced by Thiourea | Thiouracil |
|---|---|---|
| 0·08 *M* | 96 | — |
| 0·016 *M* | 55 | 60 |
| 0·0016 *M* | 5 | 5 |

An approximately 80 per cent reduction in peroxidase activity was produced by boiling the extract for five minutes.

In contrast to this order of inhibition produced by thiourea and thiouracil, milk peroxidase, prepared according to Elliott[12], was found to be inhibited to a much greater extent, as shown in Table 2.

TABLE 2. INHIBITION OF MILK PEROXIDASE ACTIVITY BY THIOUREA AND THIOURACIL

| Concentration of drug | Percentage inhibition produced by Thiourea | Thiouracil |
|---|---|---|
| 0·01 *M* | 92 | 95 |
| 0·001 *M* | 70 | 91 |
| 0·0001 *M* | 20 | 79 |
| 0·00001 *M* | 0 | 30 |

This discrepancy in the effective inhibitory concentrations of thiourea and thiouracil in these two systems suggested that there might not be any true peroxidase in thyroid and that peroxidase activity could probably be accounted for entirely by hæmoglobin. The peroxidase activity of horse thyroid was in any event small, having an average purpurogallin number (calculated for the water-extractable enzyme) of $6 \times 10^{-3}$. Moreover, the peroxidase activity of dilute hæmoglobin solutions was found to be inhibited to approximately the same extent as the aqueous thyroid extracts by boiling and by thiourea and thiouracil.

The hæmoglobin content of a thyroid extract was determined by the benzidine method as described by Ashby and Chan[13], and of horse blood diluted to give a solution of the same hæmoglobin content. The peroxidase activity of both diluted blood and of the thyroid extract was determined. In the case of the thyroid extract, the catalase content was first determined by the method of Bancroft and Elliott[7] and extra hydrogen peroxide added so that the same optimal concentration of hydrogen peroxide was available for peroxidase activity for both diluted blood and thyroid extract. The purpurogallin formed was identical in both cases, showing that the peroxidase activity of the thyroid extract (purpurogallin number of $5{\cdot}8 \times 10^{-3}$) can be accounted for completely by its hæmoglobin content. It must be remembered, however, that in the above experiments an aqueous filtrate of thyroid was used. Bancroft and Elliott found that not all the peroxidase of animal tissues is extractable with water and used a glycerol suspension of the tissue for determining peroxidase activity.

To substantiate the above findings, the total peroxidase activity, using Bancroft and Elliott's glycerol extraction procedure, of horse thyroid, perfused with Ringer through the thyroid artery in an isolated neck preparation until almost blood free, was compared with that of the unperfused thyroid from the same horse. The total peroxidase activity was decreased considerably by perfusion, the perfused thyroid having an almost negligible activity, with a purpurogallin number of $1{\cdot}0 \times 10^{-4}$. The peroxidase activity of completely blood-free dog thyroids, pooled from twelve dogs previously bled from the heart, was also found to be small, with a purpurogallin number of $4{\cdot}1 \times 10^{-4}$.

It would appear from these results that the thyroid probably contains no true peroxidase, and that inhibition of the synthesis of thyroxine in the thyroid produced by various goitrogenic agents, including thiourea and thiouracil, cannot be accounted for by inhibition of peroxidase activity. For this reason it is doubtful whether xanthine oxidase participates in thyroxine formation. Moreover, horse thyroid was found to contain none of this enzyme. Bernheim and Bernheim[14] have shown that phenyl thiocarbamide inhibits tyrosinase activity. Using the purpurogallin method of Keilin and Mann[15], polyphenolase of potato was found to be inhibited to a considerable extent by thiourea, potassium thiocyanate and sodium fluoride, but aqueous thyroid extracts were found to contain none or negligible amounts of this enzyme.

Experiments are in progress on the effect of thiourea, thiouracil and other goitrogenic agents on the cytochrome oxidase system. Although Mann and Keilin[16] have shown that sulphonamides do not inhibit cytochrome oxidase activity, it is conceivable that the total concentration of cytochrome oxidase or cytochrome *c* in the thyroid might be diminished by sulphonamides or thiouracil.

## Mepacrine Derivatives in Urine

IN collaboration with the Army Malaria Research Unit, we have developed a technique for the quantitative separation by chromatographic means of mepacrine from urine and from blood. The separation is effected on alumina and is made visible by the intense fluorescence emitted by acridine derivatives in ultraviolet light. In certain (but not all) specimens of urine from some groups of malarial patients receiving therapeutic courses of mepacrine we have observed that a yellow fluorescent band, not that of mepacrine, can be developed on the chromatogram. This band is not observed on chromatograms of normal urines from patients who have not been dosed with mepacrine. Further, a sample of urine to which an authentic specimen of pure 2-hydroxy-6-chloro-9-amino-acridine had been added gave a chromatogram exhibiting a yellow band identical with that obtained from the urines referred to above. The two bands, the one obtained from malarial urine and the other produced from a urine to which the amino-compound mentioned had been added, exhibited exactly similar behaviour on the alumina columns. Thus neither band could be eluted using methyl or ethyl alcohol, ether, benzene, chloroform, acetone, amyl alcohol, pyridine or even glacial acetic acid, whereas both bands were eluted by *N* hydrochloric acid.

A solution of the new acridine derivative was obtained by extruding the chromatogram developed from urine and extracting the band required with *N* hydrochloric acid. The solution showed the very characteristic change in fluorescent colour from yellow in acid solution to deep orange in alkali at *p*H 10·5, which is characteristic of 2-hydroxy-6-chloro-9-amino-acridine. On mixing the solution obtained from the extracted chromatogram with a solution of the authentic hydroxy-amino-compound, it was found impossible to separate the two components chromatographically.

We think it possible that the fraction *C* isolated from the urine of dogs dosed with mepacrine by Scudi and Jelinck[1], but not identified by them, may be the 2-hydroxy-6-chloro-9-amino-acridine mentioned above.

## Presence of a Labile Toxin in Yolk-Sac Cultures of Rickettsia

GIROUD[1] reported the presence of a specific toxic substance in suspensions of Rickettsia-infected organs which produced dermal lesions in rabbits. Gildenmeister and Haagen[2] found that yolk-sac cultures of Rickettsia are toxic for mice when injected intraperitoneally. We have been studying the nature of the toxin present in yolk-sac cultures of Rickettsia and summarize below some of the observations noted thus far.

Yolk-sacs of infected eggs were removed on the fourth day after inoculation, placed in buffered broth (one part nutrient broth and one part phosphate buffer *p*H 7·4), in the proportion of 1 part sac to 10 parts fluid and shaken in a mechanical shaker for 60 minutes. This process is sufficient to break up the infected cells, the rest of the sac membrane remaining intact, and yields a suspension relatively free from tissue cells and debris. The suspension is then decanted, centrifuged lightly to remove gross debris, and an opalescent fluid rich in Rickettsia obtained.

This suspension of Rickettsia when injected intradermally into rabbits gives on the second or, more usually, third day an indurated, inflamed nodule with a central necrotic area. If the suspension is centrifuged in an angle centrifuge at 4,500–5,000 revolutions for about two hours the supernatant fluid, now practically free of Rickettsia, still gives a typical skin reaction in rabbits even when diluted twenty to forty times. The injection of this supernatant fluid intraperitoneally into mice or rats is followed regularly, on the third to the fifth day, by a considerable enlargement of the spleen and liver without any Rickettsia being found even when murine strains are used. The sedimented Rickettsia resuspended in an equal volume of phosphate buffer (*p*H 7·4) and injected in the same manner give a similar but stronger reaction in rabbits, and in mice and rats Rickettsia can readily be seen in the enlarged spleen. This suspension of Rickettsia still produces a reaction in dilutions of 1 : 80, that is, it is two to four times as toxic as the supernatant fluid. If this suspension of Rickettsial organisms is frozen and thawed seven or eight times, the same reactions are obtained, although no live Rickettsia can be demonstrated either by yolk-sac cultures or by animal inoculations.

It appears, therefore, that the rabbit skin lesion and the splenic enlargement in mice and rats are caused by a toxic substance present in the supernatant fluid freed from Rickettsia, as well as in the organisms themselves. This toxin is present in cultures of both human (louse-borne) and murine (flea-borne) strains of Rickettsia.

This toxic substance, whether in the supernatant fluid or in the organisms, was found to be extremely labile. It was completely inactivated by heating for half an hour at 56–60° C., largely so at 50° C., but not at all at 40° C. The original culture suspensions diluted with an equal volume of distilled water, and kept at 37° C., lost their toxicity partly after two days and completely after three. A reduction in toxic strength occurred also after seven days in the ice box (10–12° C.).

Shaking with ether (Squibb U.S.P. for anæsthesia) for half an hour completely inactivated the toxin both in the supernatant fluid and in the Rickettsial suspension. After complete removal of the ether, no toxic effect resulted from injecting any of the fractions obtained by this treatment.

Rapid freezing and thawing of culture suspensions, seven or eight times, apparently killed the organisms, but the toxic strength of the supernatant fluid obtained after centrifugation in the angle centrifuge was enhanced. Similar treatment of the supernatant fluid, free of Rickettsia, resulted in a reduction of the toxicity. It appears that repeated freezing and thawing is to some extent injurious to the toxin, but that if the treatment is carried out when Rickettsia are present, the injury to the toxin is compensated by fresh toxin liberated from the organisms.

It seems, therefore, that the Rickettsial strains studied contain near the cell surface a toxic substance which is readily liberated into the medium in which they grow or are suspended. This toxin is highly labile, being destroyed at 56° C. in half an hour and at 37° C. in three days. From the point of view of vaccine preparation its inactivation by simple, rather brief, treatment with ether is of particular interest.

Our work has not yet proceeded far enough to indicate whether the toxins produced by the murine and human strains are antigenically distinct. Both produce the same reactions in rabbits, mice and rats, and both are equally labile.

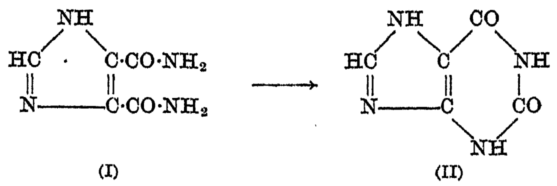
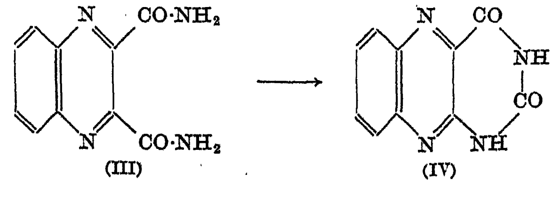
## A New Synthesis of Xanthine

BY the action of alkaline potassium hypobromite on phthalamide, Hoogewerff and van Dorp[1] obtained 2 : 4-dihydroxyquinazoline. Various applications of this intramolecular Hofmann reaction have since been reported; for example, when applied to succinamide, maleamide and pyrazine-2 : 3-dicarboxyamide, the reaction leads to dihydro-uracil[2], uracil[3] and lumazine[4] respectively. We have found that the reaction is applicable to *glyoxaline-4 : 5-dicarboxyamide* (I), which on treatment with alkaline hypobromite solution gives xanthine (II).

The ready availability of the diamide (I) makes this method an attractive synthetic route to xanthine and substituted xanthines. The reaction appears to be of a general nature, and its application to 1-*methyl*-



(I) (II)



(III) (IV)

*glyoxaline*-4 : 5-*dicarboxyamide*, which may yield either 7- or 9-methylxanthine (or, less likely, both) is being examined. In a different connexion, the reaction has been applied to *quinoxaline*-2 : 3-*dicarboxyamide* (III) to give alloxazine (IV) in 60 per cent yield.

## Loss of Inorganic Constituents on Combustion of Coal and Coke

THE standard method for preparing coal and coke ash for analysis is to burn off the carbonaceous matter by placing the sample in a silica tray contained in a muffle furnace heated to 800° C. While this procedure clearly leads to the volatilization of a proportion of the sulphur, arsenic and other volatile elements, it has hitherto been considered a valid assumption that the whole of the sodium, potassium, calcium, magnesium, silica, iron, alumina and phosphorus contained in the fuel is also present in the ash.

Observations made in the course of an investigation relating to flue solids have led us to suspect the correctness of this assumption.

To decide the issue, coal and coke were fired in a bomb such as is used for calorific-value determinations or heats of combustion. By this method all the inorganic components of a fuel are retained in the bomb. Preliminary experiments indicate that, in the case of sodium or potassium, 0–60 per cent of the original content expressed as percentage of ash may be lost when the ash of a fuel is prepared by combustion in a muffle furnace kept at 800° C. with free access of air. The bomb method of combustion for the concentration of the inorganic constituents of a fuel is a valuable technique which may reveal the presence of unsuspected elements, as well as the fact that certain elements are present in greater proportion than is usually thought. It may also reveal that determinations of elements (for example, phosphorus) by a method which depends upon their concentration in the ash by combustion of the carbonaceous material of a fuel are in error.

## Metabolism of Gill Epithelium of a Freshwater Mussel

GRAY compared (1928) the chemical mechanism underlying rhythmic ciliary movement in mussel gills with that of muscle, especially the frog's heart, and found an essential similarity. Our knowledge of muscle chemistry, especially as regards the carbohydrate catabolism, has since increased considerably, and it appears worth while now to attempt a renewed comparison.

I have studied the epithelium of the gills of the freshwater mussel *Dreissensia*, which will retain its activity and oxygen consumption unaltered for at least 24 hours in ordinary fresh water after being cut off. When the gills are shaken in the Warburg apparatus, many cells will drop off, but even these will remain active.

As a basis for comparison, the nitrogen content has proved more suitable than either wet or dry weight. 13 per cent of the nitrogen found is located in the gill skeleton, the rest in the epithelium, and the gills on the two sides of the animal correspond within 3 per cent. The oxygen consumption per mgm. N/hour at 20° C. is 18·7 µl. and the *R.Q.* 0·87 with a standard deviation of 0·04.

Ciliary movements are inhibited in about an hour by 25 millinormal sodium fluoride and in 45 minutes by 3·3 millinormal monoiodoacetamide, but not at all by phloridzin in concentrated solution. All these determinations were made at 20° and *p*H 7·5–7·6. Complete lack of oxygen stops the cilia in 30 min. at *p*H 6·5, but the effect at *p*H 8·5 is slight only. This agrees with a finding by Clark and Eggleton (1938) that the anaerobic formation of lactic acid in the frog's heart is inhibited at acid reactions.

Tests were made to find out whether lactic acid was formed in the ciliary epithelium under anaerobic conditions at *p*H 8·5, but while a considerable amount of acid was formed, as shown by the liberation of carbon dioxide in the Warburg vessels, the special test for lactic acid (Koenemann, 1940) showed no increase whatever.

An attempt was made to isolate the acid by extraction with ether after precipitation of proteins. It turned out to be volatile and to smell like lower fatty acids, but sufficient material for chemical identification was not obtained.

When the ethereal solution was shaken with normal caustic soda and this afterwards titrated electrometrically with 0·1 *N* hydrochloric acid, the titration curve showed a definite inflexion at *p*H 5, again indicating that the substance differs from lactic acid which shows a *p*K of 3·9.

Lower fatty acids are produced by anaerobiosis in certain animals, notably valerianic acid in *Ascaris* (Weinland, 1901), and several formulæ have been proposed to account for their formation from sugar. These require the simultaneous formation of carbon dioxide, which was observed also in the case of *Ascaris*, but corresponding tests on *Dreissensia* gills gave a negative result. No carbon dioxide was produced anaerobically from half the gills of four animals in 5–7 hours as compared with the other half, determined at the beginning of the period.

On the other hand, it was shown by similar comparisons that glycogen, found to make up about 1·5 per cent of the fresh weight, disappears from the gills both in aerobic and in anaerobic metabolism, but at about three times the rate during anaerobiosis. The glycogen disappearing is only partly catabolized, as reducing substances are found in the medium at the end of the experimental periods.

The respiratory quotient of 0·87 shows that some other substance than carbohydrate must be regularly catabolized, and a definite formation of ammonium proportional to the oxygen consumption was observed.

The experiments are to be continued, but so far as they go they are sufficient to show that the metabolic mechanism supplying energy for the ciliary movements in *Dreissensia* differs definitely from that of muscular contraction in vertebrates.

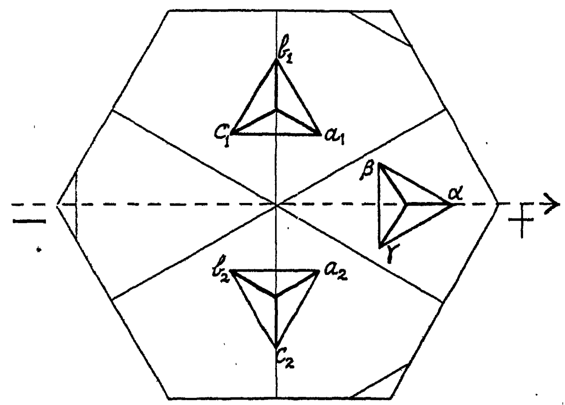
## Orientation of the Etching Figures of Quartz

THE etching figures produced on quartz crystal by hydrofluoric acid are different on surfaces cut in different orientations. The case in which the surface is normal to the optic axis is particularly interesting, since with such a surface, the etching pattern obtained consists of a great number of projecting triangular pyramids. This fact, first observed by Leydolt[1], was afterwards studied by Molengraf[2] and more recently by H. Arsandaux[3], Pan Tcheng-Kao[4] and A. de Gramont[5]. It is generally accepted that the three heights of the equilateral triangular base of each pyramid are respectively parallel to the three electric axes of the quartz, and that the three vertices of the base point towards the positive extremities of these axes when the crystal is under compression. A. de Gramont[6] asserted that the parallelism between the orientation of the elementary pyramids and the bisectors of the angles formed by the hexagonal prism of quartz is not always true and that a deviation of a few degrees may sometimes be found. According to this author, the directions of the pyramids and not those of the bisectors represent the true directions of the electric axes of quartz.

In the course of investigating the effect of ultra-violet radiations on the etching figures of quartz, I have carefully compared, by means of a high-precision micrometer, the orientation of these pyramids with the edges of the cross-section of the hexagonal prism. Measurements were performed on a number of plates cut from different crystals of Brazilian quartz. In contradiction to the observations of previous workers, the three basal heights of the pyramids are by no means parallel to the three directions of the bisectors of the angles of the hexagonal cross-section. As a matter of fact, the angle formed by them is 30°, with some possible variations of only a few degrees; in other words, the pyramids are directed to the mechanical axes rather than to the electric axes of quartz. For left-handed quartz, the directions of the three basal heights of a pyramid are orientated clockwise by 30° with reference to the positive extremities of the three compression electric axes, while for the right-handed quartz the orientation is anti-clockwise, as shown diagrammatically in the illustration.



THE REGULAR HEXAGON REPRESENTS A CROSS-SECTION OF THE HEXAGONAL PRISM OF QUARTZ. FOR A LEFT-HANDED CRYSTAL, THE PYRAMIDS OF CORROSION ARE ORIENTED AS $a_1$, $b_1$, $c_1$, AND FOR A RIGHT-HANDED CRYSTAL AS $a_2$, $b_2$, $c_2$. THE PYRAMIDS ARE BY NO MEANS ORIENTED AS $\alpha\beta\gamma$ AS GENERALLY BELIEVED.

A. Langevin[7] has investigated, by the method of etching, the quality of a number of old piezo-electric quartz plates used in the Laboratoire Curie and the École de Physique et Chimie of Paris. He concluded that the plates which gave low values of the piezo-electric constant were due to the existence of electric twinning, which could not be detected by the plate-makers of the past, who used only optical methods for the selection of plates, and that for plates free from this twinning the values of the constant were found to be very consistent, having as a mean $7{\cdot}05 \times 10^{-8}$ C.G.S. unit. In this connexion, it is interesting to mention the result of A. de Gramont[6]. This author, using the same method of selection as Langevin, found $6{\cdot}38 \times 10^{-8}$ C.G.S. unit instead of $7{\cdot}05 \times 10^{-8}$ as the piezo-electric constant of plates of the best quality. This discrepancy is too great to be accounted for by the ordinary experimental error. It may very probably be caused by the difference in the choice of direction of electric axis of the plates used; since for the determination of this axis A. de Gramont relied on the orientation of the elementary pyramids rather than on the geometrical form of quartz.

## Collapse of Determinism

MANY readers of *Nature* will have noted with interest Prof. H. T. H. Piaggio's clear and dispassionate article on the "Collapse of Determinism"[1]. Of particular interest is the statement, "But a third interpretation goes so far as to claim that the existence of causality is disproved". This, of course, was the theme of Prof. E. T. Whittaker's Guthrie Lecture[2]. His arguments, however, are open to serious criticism, and there has been a tendency to throw the onus on Von Neumann's mathematical demonstration[3]. This, however, is also under criticism[4] and there are many who, knowing how easily assumptions can lurk in analytical work, refuse to be mathematically bludgeoned. Harm can be done to the reputation of science by any who proclaim as a definite doctrine what is but a tentative effort.

In Prof. Piaggio's last paragraph he remarks, "Some philosopher-physicists welcome these conclusions as giving us a hope of escape from the tyranny of an iron law of causation and assuring freewill to mankind as well as to electrons!" That, of course, is quite true: one all too often hears the view expressed. Nevertheless, to jump to talk of the "freewill of mankind" after having just talked only of electrons, and without noticing that there has been thrown into the equations an entirely unknown function called 'mind', is 'philosophy' of a type which surely even Thomas Aquinas would not have thought worthy of consideration.

Certainly many chapters of our physical knowledge can be neatly summarized in terms of causal laws. Some other chapters can at present best be summarized in quite different ways. Many physicists feel, however, the same dissatisfaction about these methods as the directors of a successful insurance company, run on statistical lines, might feel about their knowledge of the pathology of mortal diseases. In any event it is of very great interest to know if there exists even so much as a single instance where, by common consent, causal explanations can be definitely ruled out. Until then it would appear highly necessary to refrain from imposing our preconceived ideas, whatever these may be.

---

THE views of Prof. West on the interpretation of the Uncertainty Principle are very similar to my own. However, in writing on a controversial subject, I considered it necessary to mention all interpretations given by eminent authorities. In cases where I personally was not convinced of the accuracy of such views, I used the phrase "goes so far as to claim", and when my objection was very strong indeed, used an exclamation mark. Prof. West's list of references will be useful to readers who wish to form their own opinion on a subject of great interest to both science and philosophy.

In conclusion, I wish to put forward a general argument against all supposed demonstrations of an impossibility, such as Von Neumann's. However careful the logic, at best all that has been demonstrated is that the impossibility holds for the problem as formulated. Other lines of approach, not yet considered, may correspond more accurately to the phenomena, and may lead to a positive result.

## A Siderite of the Fourteenth Century

IBN-BATTŪTAH, the famous globe-trotter of the Middle Ages, in his travels from Tangier to China and West Africa (A.D. 1325–54), on reaching Birgi (the ancient Pyrgion in the valley of the Cayster—not far from the old Ephesus in Asia Minor), some time after 1332, was asked by the local sultan if he had ever seen a 'stone' "that had fallen from the sky". When he replied in the negative, the sultan showed him the 'stone' that had fallen some time ago outside the town, and ordered four stone-breakers to strike it vigorously with iron hammers. They did so, but with no effect. It weighed about a hundredweight and was "very hard with a glitter in it"[1]. All this goes to suggest that it must have been a siderite. This fall is not mentioned in the list given in H. H. Nininger's "Our Stone-Pelted Planet"[2].

It is interesting to note that Dr. J. Astapowitsch, of the Sternberg Astronomical Institute of Moscow, in his letter to me dated July 27, 1937 (in response to my request to make inquiries about the sword presented to Tsar Alexander I of Russia by James Sowerby, made from the Cape of Good Hope siderite[3]), wrote to say he could find no trace of this sword; "but among the meteorite collection of the Lomonossow Meteorological Institute there is a yataghan (Turkish sword without cross-piece) about 60 cm. long from an unknown siderite. It belonged formerly (in the 19th century) to a merchant in Siberia".

In all probability this yataghan was made for a later sultan or Mongol chieftain from a siderite that had actually been seen to fall—*perhaps* from this Birgi one when its true nature was revealed. It would be of interest to ascertain the history of this yataghan prior to the nineteenth century. The fact that "Caliphs and Mongol Chiefs had caused swords to be forged from recently fallen meteoric 'stones'" was well known to scientific men like Alexander von Humboldt[4].

Iron meteorites that have been seen to fall are rather rare.

## Prof. W. E. H. Berwick

MAY I supplement Prof. Davenport's notice of his predecessor[1] to put on record an important service to mathematics which I was in a position to witness?

About fourteen years ago, Prof. Berwick suggested that the British Association Committee on Mathematical Tables should apply part of a bequest from Lieut.-Colonel Cunningham to the preparation and publication of a table of cycles of reduced ideals in quadratic fields. The computation of such a table is not a matter of pure routine, and could not be attempted by an operator who did not understand what he was doing; a mathematician was wanted. Fortunately, the late Dr. E. L. Ince, just returned to England from Cairo, was free to carry out the work, and he was a skilled computer as well as an exceptionally fine mathematician. The theory of ideals was a new subject to Ince, and Berwick undertook to initiate him. If, characteristically and irritatingly, Berwick underestimated the ease with which a mathematician of Ince's quality could master the elements of the theory, his own labours were the greater. He spared himself no pains, he improvised details of notation and arrangement, and he kept in close touch with the work from start to finish. The table, which appeared in 1934, properly bears Ince's name alone, but it owes a very great deal to Berwick's generous and enthusiastic help.

Stories of Berwick will be told as long as any of his contemporaries are alive to tell them; and we shall not forget that the arrogance of which we are making kindly fun was the arrogance that refused to acknowledge defeat in the presence of overwhelming physical disaster. Many times Berwick fell prone from his great height; not once did he stoop.

# GESTURE ORIGIN OF SEMITIC LANGUAGES

By PROF. ALEXANDER JÓHANNESSON
University of Iceland

IN *Nature* of February 5, I gave a summary of my researches regarding the origin of human speech as set out in my book "Um frumtungu Indógermana og frumheimkynni: On the primitive speech of the Indo-European people and their first home" (University Reykjavik, 1943). I tried to prove that the most important class of the 2,200 constructed Indo-European roots could be explained as imitation by the organs of speech of the movements of the hands. As my conclusions agreed with those propounded by Sir Richard Paget in his work "Human Speech" (1930), I published my researches. I have succeeded in adding much new material, not yet published, to my gesture theory. I was interested to see whether my conclusions for the Indo-European languages were confirmed or not in the Semitic group. I therefore undertook an examination of Hebrew (published in June in the Icelandic periodical *Eimreiðin* under the title "Hebrew and Icelandic"). The result was surprising: as many as 60 per cent of the Hebrew roots could be explained by my own rules for the Indo-European languages.

As Pre-Semitic must be a starting point, just as Pre-Indo-European is, I chose those sounds where Hebrew shows no divergence from the Pre-Semitic. I began with *d, t, th* in Hebrew. Roots in Indo-European beginning with dentals show the predominant meaning "to touch, retain, destroy (the first man either pressed his teeth together or let the tip of the tongue rest against them), extend, draw (in this case the tongue has been drawn back from the teeth to the palate)". In Hebrew many roots beginning with dentals signify "to smash, destroy, force": *dabl*, press together; *dbs*, paste together; *dvs*, tread down; *dka*, subdue; *dkh*, smash; *dkk*, break, smash; *dyk*, destroy; *dchq*, press, drive; *dqq*, smash; *tbch*, kill, slaughter; *tby*, press into something; *thphph*, beat the drum; *thqy*, clasp one's hands; *trph*, tear; *thkk*, subdue, smash, break; *thmk*, grasp, hold tight, etc. Many 'dental' roots signify to extend, draw: *dag*, be sad (get contracted); *dgl*, hoist a flag (*l* is the movement of the tongue to the palate); *dvk*, tear away; *djg*, draw up a fish; *dchh*, push (draw away); *tvh*, spin; *tvch*, cover (drag over); *tchh*, throw away; *tchch*, cover; *tyh*, lead astray; *tphch*, get expanded; *trch*, throw burdens on something, etc.

*l* in Ide. signifies especially "to move, withdraw, glide slowly, devour, lick, play, lie without movement". In Hebrew: *lhm*, devour; *lchd*, lick; *lyt*[2], devour eagerly; *lyg*[2], imbibe noisily; *lqq*, lick. Further: *dlg*, spring, play; *dlh*, hang relaxed; *dll*[1], be limp; *dll*[2], be slack, of slowly running water; *dlph*, leak, drip; *tbl*[1], immerse in water; *tla*, put a spot on something; *tll*[2], sprinkle; *thla*, hang up; *thlh*, hang on gallows; *thll*[1], heap up gravel; *thll*[2], betray (play a trick with one). Most Hebrew roots consist of three consonants, and it is clear from these and other examples that it is not always the first consonant that determines the meaning, this depending on the varying emphasis of the sounds.

*r* in Ide. signifies especially "to put in movement, make noise, erect". In Hebrew: *rvd*, roam; *rbk*, stir about; *rgy*[1], be in turbulent movement; *rhh*, be excited; *rkb*, ride. Further: *dbr*, drive; *dhr*, drive (horses); *dvr*, turn round; *dqr*, pierce; *dra*, push away; *drg*, pace, walk; *drr*, run incessantly; *trd*, drive away, etc.

*m* is formed by closure of the lips and should therefore signify "to finish, be silent", or something similar. This meaning appears seldom in Ide. In Hebrew: *dvm*, keep silence; *dmh*[2], be quiet; *dmm*, become silent (from fright); *dmn*, manure (put cover on); *tym*, taste; *thmm*, be perfect, have finished.

Of 138 roots beginning with *d, t, th* in Hebrew, the gestural origin is seen in 51 roots: *l* in the middle or final position decides the meaning in 15 roots; *r* in middle or final position in 11 roots; *m* in the middle or final position in 7 roots. Thus 84 of 138 roots (60 per cent) are evidently gestural.

Similar results are obtained by examining other sounds. The *s* roots in Ide. often signify "to run" (of water or fluid). In Hebrew: *svch*[1], flow away; *svch*[2], sink down or in; *suph*, rush; *svph*, float, swim; *sqq*, sieve (a juice); *svb*, flow, run; *skk*, sink down (of water); *snr*, conduct water; *srh*, be moist.

The relationship between Ide. and Semitic, which has been suggested for hundreds of years, is not accepted by the majority of philologists to-day. The possibility of relationship is not denied (Herm., Hirt and others). If the gesture theory is right, this doubtful question becomes clear. The first Indo-Europeans as well as the first Semitic people began to speak by imitating the signs of the hands with their speech organs. This primitive state of speech shows clearly in many Ide. and Semitic words, which apparently seem to be of the same origin (comp. Herm. Möller's comparative Ide.-Semitic dictionary). A common origin is possible. But if the constructed Pre-Indo-European language is compared with the constructed Pre-Semitic language and the different development of these two groups is kept in mind, a common origin must be at least 10–20,000 years old. A systematic research of all available Semitic material from this new point of view is now needed.

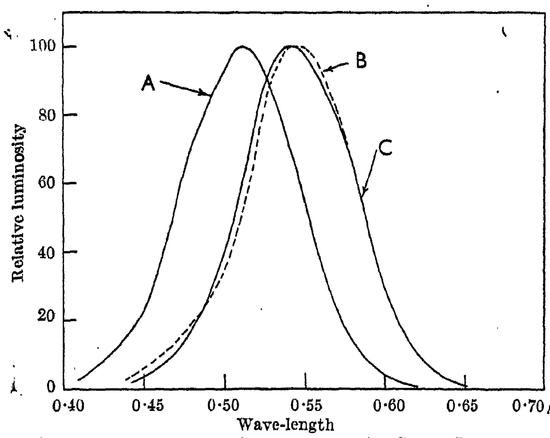
[1],[2] Different meanings of the same root.

# MONOCHROMATISM*

By DR. F. H. G. PITT
Kodak Research Laboratories

MONOCHROMATISM is a type of colour-vision deficiency in which the observer, a monochromat, can match any colour by any other colour, merely by the adjustment of their intensities. It is a very rare form of colour-vision deficiency, its frequency of occurrence in the male population being stated to be so low as 0·0003 per cent[1], as compared with 6 per cent for anomalous trichromatism and 2 per cent for dichromatism. Of this rather tentative 0·0003 per cent, nearly all the recorded cases are monochromats by virtue of their having no cone-vision. Such persons, whose defect is usually described as cone-blindness, rely solely on the functioning of the rods in the retina, and suffer from other ophthalmological defects such as low visual acuity and nystagmus. As might be expected of persons using a mechanism which, in normal persons, only functions when the eyes are dark-adapted, they suffer

* Comm. H982 from the Kodak Research Laboratories, Wealdstone, Harrow, Middlesex.



CURVE $A$, MONOCHROMAT (NO CONE VISION); CURVE $B$, MONOCHROMAT TYPE II; CURVE $C$, $G'$ FUNDAMENTAL SENSATION CURVE.

from photophobia or fear of the light. The luminosity curve for this type of monochromat is shown (Curve $A$) in the accompanying graph[2]. It is very similar to the scotopic luminosity curve for the normal eye. Whether such persons may be classed as colour-blind in the accepted sense of the word is a fine point; if they are accepted as such, then there is no logical reason why totally blind persons should not also be classed in the same way.

Recently, I came across a person who, although a true monochromat, did not suffer from the visual defects associated with the previously mentioned type of monochromat. He had passed the Army visual tests, and a confirming test showed that he had visual acuity well above the normal. His particular duties had proved him to be a very able photometrist. When tested with the Ishihara charts, the American Optical Company's Pseudo-Isochromatic plates, and a test for dichromatism and anomalous trichromatism devised by Mr. R. B. Morris of these Laboratories, he reacted as a typical protanope, and in the first two tests read the letter, which purports to detect the monochromat, with ease. He would have been classed as a protanope had he not casually mentioned that he sometimes had difficulty with the blues. A test on a Donaldson colorimeter showed that he could match any colour with any other colour, thus confirming monochromatism. A further test, performed on special apparatus, also devised by Mr. Morris, showed that his visual recovery curve, after adaptation, was almost identical with that of a normal observer and confirmed what was suspected, namely, that the observer possessed cone-vision.

By kind permission of Dr. W. D. Wright, the full luminosity curve of this observer was measured on the Wright colorimeter[3], which uses a test field subtending an angle of 2°. In the experiment, one half of the field was illuminated by light of wave-length $0 \cdot 53\,\mu$, which could be varied in intensity, and the other half by light of wave-length $\lambda_1$. The observer was asked to match the two colours as accurately as possible for various values of $\lambda_1$, throughout the visible region. This gave Curve $B$, which is similar to the protanopic luminosity curve and accounts for the fact that the observer reacted as a protanope to the three previously mentioned colour-vision tests. Colour matches, made by a normal observer for white and at various wave-lengths throughout the spectral range, were also perfect matches for this monochromat, proving that this form of monochromatism is a reduced form of normal trichromatism.

Although this monochromatic luminosity curve is very similar to the protanopic luminosity curve, it should be noted that the blue ($B'$) fundamental sensation curve[4] modifies the luminosity curve in a minor degree only. The green ($G'$) fundamental sensation curve[4] (Curve $C$) bears a like similarity, and it is therefore concluded that the observer suffers from protanopia, in which the red ($R'$) fundamental sensation curve is missing, and also from tritanopia in which the $B'$ sensation curve is missing[4]. (Judd[1] mentions, without giving any supporting evidence, that a monochromat of this class is born with protanopia and acquires tritanopia later. This acquirement of tritanopia is neither confirmed nor disproved in the case under discussion.) If the conclusion is correct, this form of monochromatism could also be classed as one of double dichromatism, and it follows that, from dichromatic data, we could forecast the possible forms of monochromatism, and, if the dichromatic data were correct, estimate the probability of occurrence. Listed below are the three well-known forms of dichromatism, designated by the names suggested by v. Kries, the reason for the deficiency[4], and the reported occurrence[1]. Another form, called tetartanopia by v. Kries, is suggested by the theories of Hering and Müller, but practical information regarding it is almost non-existent, and what is available suggests that it may be tritanopia recorded on inaccurate apparatus.

TABLE 1.

| Type | Reason for deficiency | Occurrence |
|---|---|---|
| Protanopia | Absence of $R'$ fundamental sensation | 1 per cent |
| Deuteranopia | Fusing of $R'$ and $G'$ fundamental sensations | 1·1 ,, |
| Tritanopia | Absence of $B'$ fundamental sensation | 0·0001 ,, |

From these three forms of dichromatism we obtain the following two possible forms of monochromatism, omitting, of course, the form due to cone-blindness:

TABLE 2.

| Type | Reason for deficiency | Probability of occurrence |
|---|---|---|
| Monochromat I | Absence of $B'$ fundamental sensation accompanied by the fusing of the $R'$ and $G'$ fundamental sensations (tritanopia and deuteranopia) | 0·0000011 per cent |
| Monochromat II | Absence of $R'$ and $B'$ fundamental sensations (protanopia and tritanopia) | 0·000001 ,, |

It is interesting to note that the reason for the deficiency given in Table 1 does not logically permit the occurrence of both protanopia and deuteranopia —if it did it would merely be protanopia. If deuteranopia were not caused by the fusing of the $R'$ and $G'$ sensations, a third class of monochromat would occur, having a probability of occurrence as high as 0·001 per cent, and would undoubtedly have been discovered. The fact that such a discovery has not been made supports the suggested reason for the deficiency, as given in Table 1.

According to Judd (ref. 1, p. 297), the two forms of monochromatism are postulated by one theory only, namely, that due to G. E. Müller, who classifies them as Inner Total Colour Blindness, Type I and

Type II (Type I, as postulated by v. Kries and Hering, being vaguely described as acquired total colour blindness and total colour blindness respectively). As the method of approach followed in this communication is strictly in accordance with the principles laid down by the Young-Helmholtz theory, which in a slightly modified form fully accounts for dichromatism[4], there is no reason why this latter theory should not be extended to cover monochromatism. Type I would be classified as blue-blindness with red and green fusion, Type II as blue and red blindness. Persons having Type I defect would produce a luminosity curve similar to the deuteranopic luminosity curve, but with the relatively small ordinates of the blue luminosity curve subtracted. Such persons have been reported previously, but full luminosity values do not appear to have been measured although the maximum of their luminosity curve is stated to be at $\lambda = 0{\cdot}56\,\mu$, which is in agreement with the above postulate. Persons having Type II defect will produce a luminosity curve as given in the accompanying graph. No other types of monochromat are suggested by any theory or have been reported.

It may be that the recorded occurrence of tritanopia, namely, 0·001 per cent, does not represent the true value, and that this apparently low figure is due in some measure to the fact that the usual forms of colour-vision tests do not adequately cater for this defect. If this is so, the probability of the occurrence of the two forms of monochromatism, namely, one person in every one hundred million, is also too low. Once again the nature of the colour tests normally used would tend to obscure the true figure.

# FORTHCOMING EVENTS

### Saturday, October 7

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. A. D. Lacaille: "The Northward March of Palæolithic Man in Britain".

### Monday, October 9

BRITISH MUSEUM (NATURAL HISTORY) (in the Board Room, Cromwell Road, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. J. Ramsbottom: "Edible Fungi".

CHEMICAL SOCIETY (LEEDS AREA LOCAL SECTION) (in the Chemistry Lecture Theatre, The University, Leeds), at 6.30 p.m.—Dr. W. H. Thompson: "Some Trends in Chemical Spectroscopy and the Study of Large Molecules".

### Tuesday, October 10

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Mr. H. N. C. Stevenson: "The Case for Applied Anthropology in the Reconstruction of Burma".

ILLUMINATING ENGINEERING SOCIETY (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 5 p.m.—Mr. E. Stroud: Presidential Address.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield, 1), at 6.30 p.m.—Mr. W. H. Salmon: "The Metallurgist in the Foundry".

### Wednesday, October 11

BRITISH MUSEUM (NATURAL HISTORY) (in the Board Room, Cromwell Road, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. J. Ramsbottom: "Edible Fungi".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. L. Kirke: Inaugural Address as Chairman.

### Thursday, October 12

INSTITUTE OF FUEL (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 2.15 p.m.—Dr. E. W. Smith: Melchett Lecture.

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. O. Watson: Inaugural Address as Chairman.

### Friday, October 13

BRITISH MUSEUM (NATURAL HISTORY) (in the Board Room, Cromwell Road, South Kensington, London, S.W.7), at 2.30 p.m.—Dr. J. Ramsbottom: "Edible Fungi".

(The lecture will be repeated on Mondays, Wednesdays and Fridays until the end of October.)

SOCIETY OF CHEMICAL INDUSTRY (at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Prof. A. V. Hill, F.R.S.: "Science in India".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. J. Proudman, F.R.S.: "The Tides of the Atlantic Ocean" (George Darwin Lecture).

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 6.45 p.m.—Dr. J. Coutts and Dr. Medwei: "Therapeutics in Austria and Great Britain".

INSTITUTE OF PHYSICS (SCOTTISH BRANCH) (in the Natural Philosophy Department, The University, Glasgow), at 7 p.m.—Sir Lawrence Bragg, F.R.S.: "The Physics of the Solid State".

### Saturday, October 14

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at Caxton Hall, Westminster, London, S.W.1), at 2.30 p.m.—Mr. H. Emmett: "Cinemicrography of Crystal Growth"; Mr. R. McV. Weston: "Cinemicrography in Biological Research".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT ENGINEERS for the British Guiana Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1055.A) (October 9).

TUTOR OR ASSISTANT TUTOR (temporary) IN THE DEPARTMENT OF SOCIAL SCIENCE of the London School of Economics and Political Science—The Acting Secretary, The Hostel, Peterhouse, Cambridge (October 12).

ASSISTANT IN THE MECHANICAL AND ELECTRICAL ENGINEERING DEPARTMENT—The Principal, Harris Institute, Preston (October 12).

SCIENCE LECTURER (full-time) IN THE DEPARTMENT OF BUILDING of the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool, 1 (October 13).

LECTURER (temporary) IN THE SCIENCE DEPARTMENT of the Croydon Polytechnic—The Education Officer, Education Offices, Katharine Street, Croydon (October 13).

ENGINEER (suitably qualified and experienced) for a full-time post in connexion with Production Engineering Courses, and an ENGINEER (suitably qualified and experienced) for a full-time teaching post in connexion with Ordinary National Certificate and Higher National Certificate Courses in part-time day and evening classes, in the Department of Mechanical and Automobile Engineering of Doncaster Technical College—The Chief Education Officer, Education Offices, Doncaster (October 14).

ASSISTANT SPEECH THERAPIST (whole-time)—The Chief Education Officer, 2 Cecil Road, Bristol 8 (October 14).

LECTURESHIP IN THE ENGINEERING DEPARTMENT of the County Technical College, Wednesbury—The Director of Education, County Education Offices, Stafford (October 14).

RESEARCH ASSISTANT IN THE VETERINARY LABORATORY of the AGRICULTURAL DEPARTMENT—The Registrar, King's College, Newcastle-upon-Tyne (October 14).

RESPONSIBLE TEACHER OF ENGINEERING, an ENGINEERING WORKSHOP INSTRUCTOR AND STEWARD, and a TEACHER OF PHYSICS, in the Junior Technical School and in Senior Part-time Classes at the Batley Technical College and School of Art—The Director of Education, Education Offices, Batley, Yorks. (October 16).

CHIEF ENGINEER for the Town Council of New Amsterdam, Berbice, British Guiana—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2296.A) (October 16).

CHEMICAL ENGINEER, experienced in design and installation of chemical manufacturing plant, for supervisory post in London—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2292.XA) (October 16).

HEAD OF THE CHEMISTRY AND APPLIED CHEMISTRY DEPARTMENT—The Principal, Royal Technical College, Peel Park, Salford, 5 (October 16).

LECTURER (full-time) IN CHEMISTRY—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (October 16).

ASSISTANT MASTER IN MINING SUBJECTS in the Coalville Mining and Technical College—The Director of Education, County Education Office, Grey Friars, Leicester (October 17).

TEACHER to take charge of BIOLOGY CLASSES and to assist with ELEMENTARY SCIENCE SUBJECTS—The Principal, Harris Institute, Preston (October 18).

PROFESSOR OF PHYSICS—The Registrar, University College, Singleton Park, Swansea (October 18).

ASSISTANT LECTURER IN THE MECHANICAL ENGINEERING DEPARTMENT of the Belfast College of Technology—The Director of Education, Education Office, College of Technology, Belfast (October 30).

CHADDOCK CHAIR OF ECONOMICS—The Registrar, The University, Liverpool (December 29).

LECTURER IN GEOGRAPHY at the Furzedown Training College (evacuated to the University of South Wales, Cardiff)—The Principal, 29 Corbett Road, Cathays Park, Cardiff.

TEACHER (male, Graduate) OF MATHEMATICS with, if possible, subsidiary GEOGRAPHY—The Principal, Technical High School, Cole Street, Scunthorpe.

# FOOD HABITS

IT is no light undertaking to make a scientific study of the food habits of a nation, especially when that nation is at war and is sending vast quantities of its basic foods to its allies in a world which is also at war. The United States Committee on Food Habits is one of two committees set up in 1940 by the National Research Council at the request of the National Defense Advisory Commission, as part of the plan for mobilizing science for defence and war effort. Its report is published under the title, "The Problem of Changing Food Habits"*.

The task of the Committee was to study the psychological and cultural pattern of human nutrition, while the other committee appointed at the same time (the Food and Nutrition Board) had the task of dealing with the biochemical and physiological aspects of this problem. The aim was not merely to tell us why we eat what we do eat, but also to guide the food habits of various kinds of people in the direction required by health and national and world needs. This study requires the consideration of economics, culture, tradition, agriculture, national and individual psychology and other factors which govern the consumption of food by communities or individuals. As the preface to this brochure explains, little had been done when the Committee was appointed to study the relation of culture and behaviour and personal traits to food habits, and it had a pioneer job. It had to collect existing knowledge of what foods were liked and disliked by different kinds of people, to stimulate research and to be ready to advise. Dr. Carl E. Guthe, the chairman, contributes a detailed history of the Committee, and Miss Margaret Mead, the executive secretary, reviews the work done.

One of the Committee's first tasks was to organize the mass of existing knowledge, which ranged from studies of soil agronomy to studies of historically changing diets, the relationship between purchasing power and foods eaten, the relation of learning to eat with other types of learning and such medical data as those supplied by the study of gastro-intestinal diseases and other illnesses which profoundly affect food consumption. At the same time new methods of acquiring further knowledge had to be devised. The study had to be world-wide, and the effects of lend-lease and nutritional relief of other countries had to be included. Gifts of white flour for the relief of famine might, for example, inculcate in a population accustomed to eat whole grains a habit which would have disastrous effects on their health in the future. The way in which foods substituted in war-time for normal ones are presented may affect the post-war acceptance of those foods. The enforcement of nutritional standards may have all kinds of repercussions. The giving of emergency food tickets to children may, for example, break down parental authority, with undesirable results in communities in which this authority is traditionally or culturally strong. The whole cultural picture must be considered

* Bull. National Research Council, No. 108: The Problem of Changing Food Habits. Report of the Committee on Food Habits, 1941–1943. Pp. 177. (Washington, D.C.: National Academy of Sciences, 1943.)

before changes are introduced which may be desirable nutritionally, but may be socially undesirable.

The Committee's method has been to approach the problems largely through the conceptions of cultural anthropology; food habits were seen as "the culturally standardized set of behaviours in regard to food manifested by individuals who have been reared within a given cultural tradition". But these behaviours are related to other standardized behaviours in the same culture. Preference for meat or aversion to milk were not, for example, treated as isolated items, but were referred to the total complex of behaviour which constituted the food habits. Methods of changing food habits are similarly related to psychological factors of learning. The cultured individual reacts both to the food itself and to its production and distribution.

There was no immediate prospect of financing intensive cultural studies of American food habits. Methods for the quick appraisal of some of the more important factors were therefore devised by Prof. Kurt Lewin, of Iowa State University, who contributes an account of the study which he directed by means of a questionnaire addressed to 2,300 Iowa school-children and by interviewing housewives; and Dr. Franklin Dove devised a method of defining the content and pattern of regional food practices. These studies, and others of resistance to change, rationalizations of resistance and so on, have made it possible to identify various social-psychological characteristics of the American food pattern. Examples of these are the tendency, in counties with a Puritan tradition, to use food for purposes of reward and punishment; or the conflict between the emphasis in the southern United States upon personal taste rather than upon health and duty, with consequent catering for the individual tastes of each member of the family; and the emphasis in the north upon "moral overhauling" of the behaviour of each member of the family.

Studies of emergency feeding showed that the most practical way of avoiding giving offence to anyone in a mixed group was to cook single foods with a minimum of seasoning and to serve all condiments separately. The contemporary American cafeteria and methods of self-selection of meals are examples of social institutions well adapted to a variety of incompatible food habits. "The attitude of many European peasants who treat bread as sacred and guard against a single crumb falling on the floor has vanished in a country in which food was the certainty and money the uncertainty"; for, until 1942, very few Americans under forty had had the experience of having money for food while the food was not obtainable. The study of food habits is also necessary for the understanding of subcultural groups in the United States. To this subject Natalie F. Joffe contributes an interesting paper. This aspect must also be studied because the United States will send food to other countries, to the food habits of which these rations must be related.

The study of the number, form and composition of meals reveals some interesting features. A nutritional substitute for meat may, for example, be milk, but culturally the container may have been substituted for the thing contained, so that food which is not nutritionally a substitute for, say, protein, may be accepted if it is put on the table in a casserole or other suitably shaped container. If the shape and size of the container of food is so important to some human beings, they would seem to resemble some animals in this respect, for the farmer knows that he is asking for trouble if he gives his pigs or hens, for example, their food in containers to which they are not accustomed, or if he puts these containers in a new place.

Industrialists will be interested in the section which deals with the effects of altering the time of a meal or of changing the name given to it. Prof. Lewin, discussing this question, claims that people eat according to the clock and that, if they start work at noon, breakfast foods, such as fruit juice, eggs, cereals and milk, may be omitted from the diet. Two other papers also discuss this and other effects conditioned by hours of work.

Prof. Lewin's study further considers the effects of shopping habits, to which must be added the effects of the ration card, the queue and similar factors. If Prof. Lewin's contention is correct that the person who buys the food controls the diet, increased shopping during the War by men or children may affect the content of the meals considerably. In Great Britain this conclusion will, no doubt, be disputed.

Prof. Lewin also provides a discussion of motives for buying different kinds of food, among which, of course, are the amount of money available, the price of foods and the conflicts between these and other economic factors and the ideals of health and cultural tradition. A Czech or an American of Czech origin and a Negro will omit different foods as a result of the conflict between these factors, and there will be similar differences between the decisions of the Jew and the American of German or Anglo-Saxon descent. Meat, concludes Prof. Lewin, is the "most typical husband's food", and this introduces another complication. For whom in the family is the food to be bought? If the husband is a keen gardener, as, for example, the Czech in the United States apparently is, will the family eat more fresh garden produce? If it is true that a man acquires his personal food tastes within the family, he will carry these to public eating places and so affect their catering. But it would be interesting to find out whether this often, or indeed ever, happens in Great Britain; and how much the home catering can be affected by family experience in a public eating house.

Another series of questions arises out of the consideration of the housewife's knowledge of cooking and food values and the degree of her influence on the home. Prof. Lewin suggests as a partial explanation of why we eat what we do eat the "channel theory", which amounts to the self-evident proposition that we do not eat at home what does not come into the home. This forms, nevertheless, the basis of his study of how food comes to the table and why. Prof. Lewin gives paramount importance to the view that once food is on the table, most of it

will be eaten by some of the family. This view also will be challenged by some British authorities. Nor should we forget the importance of the way in which food is served. The effects, for example, of the method of serving it on individual plates are discussed by the Committee on Food Habits, and all of us have probably suffered—or benefited—from the system of training children to eat up what is on the plate, without adequate consideration of what the physiological or mental results may be.

In a leading article in the same issue (p. 47), *The Lancet* gives the salutary reminder that it was not science that made our forbears healthy on the food which they liked; science only enables us to understand why they were healthy. The primary error that we have made, says Mr. F. Le Gros Clark (also in the same issue of *The Lancet*, p. 55), is that of looking upon food habits as a health problem. To the public, milk, for example, is a beverage, and we have almost succeeded in converting it into a medicine. Neither Lord Horder nor Mr. Le Gros Clark is, of course, seeking to belittle the value of scientific knowledge about food; they are both, like the United States Committee on Food Habits and the British Food Education Society, concerned to create a gradual and irreversible change in food preferences; but the views of Lord Horder and Mr. Le Gros Clark will be welcomed for their practical common sense.

The study of the influence of methods of preparation of foods leads the inquirer into many complex problems. *The Lancet* (542, April 22, 1944) has pointed out, in a discussion of a memorandum on hospital diet issued by King Edward's Hospital Fund for London (1943), that the hospital ward offers an unparalleled opportunity of giving people experience of the value of rightly chosen and properly prepared food. The King's Fund memorandum lays down the principle that the food service of a hospital should be one of its essential remedial services; and most of us will agree. The remarkably good recipes for war cookery issued in Great Britain by the Ministry of Food and other agencies during the War have taught the people a great deal about the choice and preparation of meals which are both adequate and appetizing. Lord Horder, in his address to the Food Education Society last June (see *The Lancet*, 53, July 8, 1944), has reminded us that the science of nutrition is a young one and that we should not strain too far the few facts of which we seem certain. Balance the day's diet, by all means, he says, but it is not necessary to balance the individual meal. He also said wise things about white and other kinds of bread.

The many other questions raised by the American report cannot be discussed here. It is already possible, says Miss Mead, to predict the general lines which resistance to, or acceptance of, proposed changes in food habits will follow; but recommendations of methods have to be related to the whole complex of the War and to the cultural, social and individual ideas about food of a variety of peoples. She suggests that, during the War and the immediate post-war period, two tasks must be tackled. One is to maintain the health of the people by the skilful use of existing food supplies; the other is to present the increased knowledge about the use of foods in such a way that it does not become associated with wartime deprivation and therefore is not rejected later on. The additional long-term task, in the United States, is to alter American food habits so that they are based upon a tradition which embodies science and yet are sufficiently flexible to incorporate new scientific results. Altered production and distribution of foods will not by themselves effect this. Nor will authoritative pronouncements effect it, for they tend to breed regional conformity rather than intelligent flexibility. The responsibility rests on those individuals who plan what others will eat. New knowledge must therefore be conveyed to the woman on the farm, in the village and in the city. Mr. Le Gros Clark (*loc. cit.*) would seek the point at which social preferences are most readily influenced, and suggests that the school canteen, aided by committees of parents, could be developed gradually into an institution for the education of public tastes. The pressing need, writes Miss Margaret Mead, is for the integration of the techniques which have been devised for dealing with various aspects of these problems.

## ENGLISH AGRICULTURE, NOW AND AFTERWARDS

(1) The Farm in the Fen
By Alan Bloom. Pp. 192+20 plates. (London: Faber and Faber, Ltd., 1944.) 10*s*. 6*d*. net.

(2) This Farming Business
By Frank Sykes. Pp. 160+8 plates. (London: Faber and Faber, Ltd., 1944.) 8*s*. 6*d*. net.

FORTUNATELY for the countryside of England, there have always been men who have felt the urge to reclaim heaths, moors and wastelands and bring them into agricultural use. Reclamation went on vigorously during the Napoleonic Wars, during the War of 1914–18, and during the present War; it has hitherto been essentially an emergency activity. Unfortunately, a great deal of the land thus brought into cultivation has been allowed to go derelict again, so that the whole of the capital embarked has been lost. Reclamation on the grand scale has been undertaken during the present War and a fascinating account of one of these enterprises has now been published.

Mr. Alan Bloom is a born reclaimer. He began as a nurseryman producing flowering plants for gardens, and having had difficulties owing to dryness of his soil, he looked out for a fen-land farm to which he might transfer the moisture-loving varieties. In 1939 he found a farm in the Burwell Fen which was certainly not short of water; it had, however, been badly run down. Next to it lay Adventurers Fen, which, though at one time cultivated, had long since been abandoned, and had reverted to a water-logged waste. It was a familiar story. Until recently, drainage had been the responsibility of a number of small local bodies, none of them possessing resources or power to do the work properly; as the farms fell in value, so their resources dwindled and less and less drainage could be attempted. Seeing the hopeless-

ness of the situation, some of the owners leased out their land to turf diggers, who left the surface so badly pitted and lowered that any faint chance of restoration to agriculture vanished.

Mr. Bloom was fortunate in beginning work in 1939, when the threat of war compelled the Government to increase the output of food. His financial difficulties disappeared when the War Agricultural Executive Committee not only ensured the proper drainage of his farm of two hundred acres but also appointed him its agent to reclaim another two hundred and eighty-six acres of Adventurers Fen.

Mr. Bloom has a keen sense of detail and describes vividly the draining and the ditching; the work was not without danger, and, indeed, one man lost his life through the caving in of peat and mud, which engulfed him; a horse also was lost and two tractors only narrowly escaped. The removal of the water was followed by the clearing of the scrub growth and by such levelling as was possible. The land was then ready for ploughing, but another difficulty was met: buried in the fen just below the surface were numbers of oaks, ranging up to 50 ft. or more in length, and, of course, very heavy. Much labour and ingenuity were expended in getting these out. Finally the land was sufficiently friable to allow of cultivation.

The crops grown were wheat, sugar beet, potatoes and smaller areas of peas, feeding linseed, buckwheat, etc. Only little grass could be kept for the cattle. The soil lacks phosphate, which so far cannot fully be supplied; it shows signs of manganese deficiency; it would be interesting to know whether there is a copper deficiency as in somewhat similar soils in Holland and North Germany.

In the end a considerable amount of food was produced; it was so badly needed that the cost did not matter. The land, too, is back into proper shape for farming, though, of course, it will always need precautions against weeds, against wind erosion, and against flood and fire. But, as stated above, this kind of thing has been done before. Will Adventurers Fen revert once more to the wild after this War is ended, and the great cost of reclamation simply be lost? The difficulties of keeping reclaimed land in cultivation were ably discussed by Dr. C. S. Orwin some years ago in his account of the reclamation of Exmoor forest. They are great, but they are not insurmountable, and it is devoutly to be hoped that the prodigious amount of labour and money expended in land reclamation during these past few years will not be wasted.

The second book on our list is also a record of splendid achievement in food production, but in very different circumstances. Mr. Sykes, like Mr. Bloom, came new to farming and proved to have a great flair for it. In 1927 he took over the tenancy of 1,200 acres of corn- and downland near Salisbury. Prior to 1914 it had maintained four flocks of sheep and employed a staff of twenty men; then during the War years of 1914–18 there had been much ploughing up and corn growing: the productivity ultimately fell so much that the farm had to be abandoned. Mr. Sykes began by laying it down to grass on which he kept Cheviot ewes and dairy heifers and so was able to make a living for himself and the few men still retained. Later he took another similar farm. By 1935 prices were recovering and he was able to improve his system: he had been impressed by what he had read about the advantages of breaking up and reseeding pastures; he tried the method and found that it succeeded. So he decided to adopt ley farming, and as the natural conditions are suitable he has been able greatly to increase his output of food in consequence.

Mr. Sykes briefly but ably summarizes his methods, and the book is a valuable guide to any young farmer on chalk soils. For seeding the ley he uses a mixture of Aberystwyth rye grass (16 lb. per acre *S*23) and white clover (2 lb. *S*100) on good land, while for poor hill land he adds 5 lb. per acre cocksfoot. He grazes the herbage in the first year and cuts it for hay in the second; he ploughs up directly there is any sign of the appearance of turf. This is done in autumn, and wheat is sown immediately without any break for a bastard fallow, of which he does not approve. A good crop can be obtained relatively cheaply—about £2 per quarter at present prices. But a second crop of wheat on the same land costs much more to produce, and Mr. Sykes brings out clearly the steep rise in cost as the output of wheat is increased. Like many other farmers, he wishes there was a good autumn barley. He has considerable faith in flax, but not much in sugar beet which, in his view, could never stand against sugar cane in free competition. Potatoes he regards as a crop for the specialist, owing to the extent to which it is becoming mechanized; market-garden crops are beginning to interest him, but he prefers to say little about them at present.

Mr. Sykes sets out his views on the future of British farming. The present enormous output of food from our farms is, of course, being achieved regardless of cost: Mr. Sykes states that the only business part of farming now is filling up forms and keeping the Inland Revenue at arm's length. But it will not always be so, and before long the cry will be for cheaper food. Mr. Sykes admits that we could not completely feed ourselves so cheaply as we could import the food, but he thinks that wheat production at some level between pre-war and present output could be maintained at a contract price of 50*s*. per quarter, the wage-rate being as at present. But the British corn-grower cannot stand up against the competition of soil exploiters, or of subsidized imports.

Milk is likely to remain one of the leading farm products, and Mr. Sykes has much to say about its production in greater quantity, in cleaner state, and at lower cost. The present average annual output per cow he puts at 400 gallons, but this could be greatly increased; 1,000 gallons is not an uncommon yield. The trouble is that milk yield is inherited from the sire, and few recorded sires are available. If artificial insemination were adopted much better use could be made of them. He has much to say about the working of the 'clean milk' campaign, tuberculin testing, attested and accredited herds, etc. On individual farms improvement has been effected, but the consumer (who paid the cost) gained little because unclean milk got mixed in during transport. Three diseases, tuberculosis, mastitis and contagious abortion, play havoc with our dairy herds, and he puts the average life of the dairy cow in the milking herd at only two or three years. (The usual figure is higher.) Widespread improvement is difficult because 'reactors' are often sent to market and bought by some other dairy farmer looking for a 'bargain'. One of the great advantages of dairy farming is that it is well suited to the small farmer—and England is and always has been a land of small farms.

Ley farming would also improve our capacity for lamb production, and it should be possible to carry one ewe to the acre. On the other hand, Mr. Sykes

is not sure that our pre-war output of poultry and eggs can be maintained at anything like pre-war prices. The conditions were rather special and may not recur. Our farmers were guaranteed 45*s.* per quarter to produce wheat. But foreign wheat was coming on to the market at much lower rates. Mr. Sykes states that French wheat, for which the French Government had paid the French peasant 60*s.*, was sold in England at 18*s.* per quarter. Much of it was bought by poultry-keepers and converted into cheap eggs. However, with more folding of poultry on the farms, and better arrangements for collecting, grading and storing the eggs, Mr. Sykes thinks that a good and regular supply of poultry products can be assured.

Mr. Sykes is no advocate of self-sufficiency, but he considers that imports should be controlled by an import board. Under this would function production boards for the different farm products on which would be represented producers, retailers and consumers: these boards would fix prices and production levels, improve the quality and the marketing of the products. A national marketing board would correlate their work. He does not, however, wish to see the War Agricultural Committees continue in existence, still less does he want control by officials. The poor farmer must obviously be eliminated, but this will proceed automatically if the production boards insist on adequate standards of quality: to these the poor farmer never could conform.

The book is refreshing and full of good points. A few slips in the chapter on manuring should be corrected if another edition is printed.

A word of praise is due to the publishers, who in spite of war-time difficulties have presented both books in very attractive form and furnished some admirable illustrations. E. John Russell.

## ECONOMIC STUDY OF PLANNING

### The Road to Serfdom

By F. A. Hayek. Pp. viii+184. (London: George Routledge and Sons, Ltd., 1944.) 10*s.* 6*d.* net.

THERE are some who regard this War as liable to become economically a war against the middle class, as indeed the War of 1914–18 was as touching the middle classes in Germany. Even were this the case I do not know that it would greatly awaken my sympathy. By their chauvinistic short-sightedness they have 'asked for' their own extinction. They correspond to the national phase in human development. They made the National State and will perish with it. However, Prof. Hayek undertakes to show us the way by which they and others will travel to that total servile State, which he, along with Dr. Friedmann, sees as the next phase.

Prof. Hayek does an excellent piece of work on the analytical side. Primarily an economic study of what is involved in 'planning for all', it has some of the sombre quality which distinguished Otto von Seeck's great study of 'the rotting away of the best' at the time of the middle Roman Empire. The aristocratic quality of liberty, such as Signor Croce applauds, is at a discount. Prof. Hayek reminds Englishmen of their own distinctive tradition in which they have now lost confidence. He quotes Milton: "They who seek nothing but their own just liberty have always the right to win it". Milton adds, "wherever they have the power". He indicts Profs. Laski, Mannheim and Carr as "the totalitarians in our midst", and he doubtless would add other names such as those of Messrs. Crowther, Haldane, Bernal, Strachey *et al.* Economically Prof. Hayek points out that planning of production means planning of consumption and of "the means of all our ends"; that when a man's life is so planned he loses his economic liberty, not sometimes, as under capitalist unemployment, but always. When material life is controlled, as the Socialists also have said, political liberty is an empty name. John Smith is one forty-millionth of a sovereign and one whole slave. The abstract rule of law departs and the tyrannous 'rule of men', the Hitlerite-Stalinist administrative State, arrives, in which law is subject to considerations of particular effects, *raison d'état* and bureaucratic convenience. Instead of a man planning his own life, it is planned for him (so much more 'efficiently') by the State. He is allocated a 'status', as in the later socialist days of the Roman Empire. As, indeed, Aristotle said was inevitable, "a democracy may set up the most complete despotism imaginable".

Where Prof. Hayek, Dr. Erich Fromm, Peter Drucker and (if I may mention him in the same breath) Prof. Mannheim are weak is on the constructive side. Prof. Hayek agrees with the Marxists that planning must be all or nothing. He therefore wants *laisser-faire* and recognition of "money as one of the greatest instruments of freedom". In Prof. Mannheim's middling position that we can "plan for freedom", he sees only words. I have objected to this Marxist 'die-hardism', and I agree no more with Prof. Hayek or with Mr. Belloc, whom he cites. His is the old argument of Locke (and Hegel) that private property is morally necessary, for those who have got it, as a 'defence of personality'. This is very true but not true enough. Those who control the economic plan can persecute, even to death by starvation—"who does not obey shall not eat"; yet the final liberty remains spiritual and includes the power to refuse co-operation. The point is more than academic. It is being demonstrated by Gandhi to-day, and by the Danes on strike in Copenhagen. It is true that Gandhi only confronts the British Raj, full of Victorian moral inhibitions, and not the tyranny of the modern totalitarian State; but the same methods would probably apply.

The mass of men tolerate more readily death in war than unemployment. There is nothing fine in unemployment. It may well be true, as Dr. Fromm suggests, that the mass of men (perhaps unlike the American pioneers) far prefer security to liberty, of which they are no little afraid. The record of history seems to bear this out. It may be bad for progress that this should be so, but progress was always, as Mill said, of a few. If, however, we decide deliberately to move for a civilization less dominated by large-scale heavy industry and more by peasant farming, then the quite inevitable tendency in machine industry to plan for security will be thrust into a more proper perspective against the freedom of the small owner. The real enemy here lies in war, with its tendency to subordinate all to totalitarian planning, even architecture, even child-bearing. Conversely we discover the imperative necessity for liberty of peace—not this or that political gadget but, as Gandhi has insisted, actual peace—shall we say the flat refusal in the future to fight either the U.S.A. *or* the U.S.S.R.? The Master of Balliol has described the prescription of Prof. Hayek and those who think with him as the certain recipe for revolution. Man,

being made as he is, he is not a liberty lover except in quite small doses. I agree with Dr. Lindsay. But I submit that the Mahatma sees further than either of them. At least the Indian experiment remains one of the few radical ones, that escapes from the compulsions of domination-politics, in our days. I cannot conclude without noting Prof. Hayek's support of that federal union of the whole West, with an Anglo-Saxon nucleus, which I have urged for many years and which now also receives the support of Mr. Walter Lippmann in his "War Aims".

GEORGE CATLIN.

# CERAMICS AS INSULATING MATERIALS

**Porcelain and other Ceramic Insulating Materials**
By Dr. Ernst Rosenthal. Vol. 1: Raw Materials, Manufacturing Processes, Testing and Characteristics. Pp. xii+287. (London: Chapman and Hall, Ltd., 1944.) 28*s*. net.

THE pottery industry is almost virgin territory for the worker in applied science. Despite the trails blazed by J. W. Mellor in Great Britain and H. Seger in Germany, there are still wide tracts quite unexplored. There is still no institution of university status in Great Britain offering a full-time course in ceramics, and the number of qualified chemists and physicists engaged in the pottery industry together scarcely exceeds a baker's dozen. Things seem to be somewhat better in the United States, and there is a number of universities and State colleges at which full-time courses may be followed and degrees obtained in ceramics, usually in the engineering department. Faced with this position, the prospective writer of a book dealing with the scientific and technical aspects of the manufacture and applications of pottery must choose between two alternatives: either he writes for the ceramist and accepts the joy of writing as his main recompense, or he seeks to write a popular work, broadening the range and almost inevitably lowering the level. Dr. Rosenthal has neatly avoided this dilemma by writing a book on ceramics, not primarily for the potter, but for the much more ubiquitous engineer.

The book constitutes a remarkable *tour de force* for a man of science writing in an adopted tongue. Comparatively little trace of foreign terms remains, though the absence of hyphens causes the phrase "felspar containing steatite" to mean just the opposite of what the author intends it to convey, and the extension of this form to "each clay substance containing material" is likely to bewilder the average English reader until he has had time to sort it out. These constructions and some mistranslations, such as precipitation for sediment, subsequent for consecutive, compressor for press, feldspatic for felspathic, and talcum (though not invariably) for talc, might well have been eliminated by more conscientious proof-reading. A few misspellings have crept in by the same door, though "vacuum plugging" is obviously an invention of the printer's devil.

Where numerical data are given, the author has apparently taken over without conversion the units adopted in the original publication, thus compelling the reader to do a fair amount of mental arithmetic if he wishes to compare the figures given in different tables. Still more disturbing to the pedant will be the scant attention which has been paid to uniformity and accuracy in the dimensions of physical quantities. Impact strength appears at least once as cm. per kg., while in the footnote to a table of tensile strengths we learn that 100 lb. per in.$^2$=70·3 gm. per cm. or 7·03 kgm. per cm.$^2$. Power factor is stated to be expressed as $\cos\delta=\sin\delta$ (though given correctly later), and phase angle between current and voltage as 90 per cent. We are informed that thermal conductivity of ceramic materials is usually expressed in K. cal. per m.$^2$ h. °C. on the Continent, and in Cal. per sec. per cm.$^2$ per °C. in American literature; but the variants K. cal. per m.$^2$ per h. °C. and Watts Cm.$^{-1}$ (deg. Cent.)$^{-1}$ also occur in the book.

The statement that slop stone at 26 oz. per pint contains 18·33 lb. stone per peck is an obvious arithmetical slip, but the Brongniart formula looks strange with the plus and multiplication signs interposed. As the whole basis of body compounding by the wet method depends on an accurate knowledge of specific gravity (pint weight) one surmises that the slip maker whose pint measure held *approximately* 20 oz. would soon be parting with his can or his job. The mineralogist will be surprised to read that calcium carbonate occurs in Nature as whiting. Flint as a general term for silica is American rather than British practice. Photomicrographs are mostly called microphotographs in the book—a common error.

All too frequent blemishes of the type indicated above should not blind the reader to the merits of the book; it contains too much of value to be lightly dismissed. The author's wide experience both as investigator and manufacturer invests what he has to say with authority, and the persistent reader will be well rewarded for his pains. Chemical and physical formulæ have been reduced to a minimum. The engineer with even a smattering of chemistry will find no insurmountable barriers, while at least 75 per cent of the book will be comprehensible to 95 per cent of potters. Every pottery manufacturer interested in vitreous bodies or tunnel oven firing, to mention only two 'actualities', would be well advised to read it. There are few ready-made recipes for bodies or glazes, and no specification of the ideal tunnel oven, but much thought-provoking discussion of principles and practice.

Each material has its own characteristic limitations and possibilities which, in turn, influence design. The engineer who thinks that ceramic products might provide the answer to some of his problems should consult the ceramist at an early stage in development. In this connexion the sections dealing with shaping methods and tolerances will be of interest. Though not stated explicitly, the book is primarily addressed to electrical engineers. It can, however, be heartily recommended to engineers in general (the chemical engineer is apparently to be catered for in a subsequent volume), many of whom would probably be surprised to see the numerous photographs of ceramic products in the book—some small and complicated, others large and evidently extremely robust.

In the preface to his book Dr. Rosenthal expresses the view that ceramics could further advance industrial progress if their excellent technical characteristics were more generally known. Is it too much to hope that this view will be shared by those responsible for rebuilding and rehousing schemes?

MARCUS FRANCIS.

# LITERATURE AND SCIENCE

## Science and Criticism

The Humanistic Tradition in Contemporary Thought. By Herbert J. Muller. (Dwight Harrington Terry Foundation: Lectures on Religion in the Light of Science and Philosophy.) Pp. xiv+303. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1943.) 25s. net.

PROF. MULLER, who is a professor of English, is perturbed at the incoherence and lack of standards in modern literature and modern life; as well he may be. He here expounds and criticizes (with good knowledge, sound sense and a pretty wit) many recent scientific theories in all branches, apparently because he thinks a better knowledge of them would improve literary standards. It is almost as though he thought "Macbeth" would be improved by substituting three psycho-analysts for the witches, or "Paradise Lost" by introducing Einstein's theory and the expanding universe.

Perhaps this is a parody of Prof. Muller's intentions. He says himself that he has tried "to make really available, for the purposes of literary criticism, the revolutionary findings in the natural and social sciences, with which critics are generally familiar but of which they make only superficial, incidental or erratic use". If this means anything it can be applied to a concrete case. From the preface to Shaw's "Doctor's Dilemma" it can be seen that his knowledge of medical science is less than superficial because he misconceives the whole character of scientific investigation. Nevertheless the play portrays excellently the contrasts between the medical humbug, the surgical 'go-getter' and two types of honest medical man. Shaw is a good enough observer to reproduce the general flavour of current medical jargon and that was all the technical knowledge he needed. Could any amount of medical knowledge have made any appreciable improvement? As to literary criticism, do critics differ in their judgment of this play according to the extent of their medical knowledge? Surely the knowledge Shaw chiefly needed was of the difference between an honest man and a humbug; knowledge outside the scope of science. It is remarkable that the feeblest character in the "Doctor's Dilemma" is the young artist, who is just stock stage property.

Prof. Muller has been strongly influenced by the philosophy of Dewey and shares his robust good sense, proper suspicion of high-flown theory and respect for the factual and concrete. But even more than Dewey he is shaky on fundamentals. Though he has acute criticisms to make of some recent advocates of 'scientific humanism', he seems to share their inability to distinguish between matters of fact and standards or criteria of value. In literary criticism he obviously has standards which are not those of the average man or the majority, nor are they just expressions of private likes and dislikes. He gives no account of his own standards, but it is clear (pp. 1, 47 note, 283 and elsewhere) that for him they are absolute. Yet, when it comes to other people's absolutes and standards, he takes a severely 'relativist' and 'naturalist' view, urging that every judgment is relative to a particular concrete situation, that nothing has value except to some individual who values it, that it is difficult to define standards of value, perhaps impossible. All these assertions are correct; but if they suffice to demolish other people's standards they demolish his own. Confusion about standards seems to be the key to the writing of this book. The author sees that literary judgments are too often based on caprice or convention or defiance of convention that is equally conventional; that literary standards are hard to discover and impossible to define. Science, on the other hand, seems to possess its own standards, definite and easily understood. Therefore if only the literary man could borrow scientific standards all would be well.

Literary men may learn from this book that if they ride scientific hobby-horses they do so at their own risk, but scarcely anything else. Men of science may benefit by learning what an intelligent, critical outsider thinks of some of their activities. Those who theorize in the realm of the social sciences may benefit by some wholesome criticism.

A. D. RITCHIE.

# A TEXT-BOOK OF ZOOLOGY

## Thomson's Outlines of Zoology

Revised by Prof. James Ritchie. Ninth edition. Pp. xii+1021. (London: Oxford University Press, 1944.) 28s. net.

THE ninth edition of the "Outlines of Zoology" appears after a lapse of fifteen years, and is the first since Sir Arthur Thomson's death. In the preface, Prof. James Ritchie expresses his appreciation of the opportunity afforded to him of paying a tribute to his former teacher "by endeavouring to prolong the usefulness of his widely known Outlines". He was assisted by Dr. Gresson and Mr. G. F. Friend.

In considering a new edition, as opposed to a new book, three questions confront the reviewer. Does the new edition preserve the original character of the book? Have the emendations been fitted into the whole so that the balance has been preserved and overburdening of the text avoided? Has the subject-matter been brought up to date? The outstanding feature of Sir Arthur Thomson's book was that the blending of animal structure and function with a broader 'natural history' made the book readable, and presented the subject to the student so pleasantly that it encouraged him to explore both the main site and the nooks and corners of this vast field of study. Prof. Ritchie has preserved and improved this feature and his re-arrangements do not disturb the flow of thought. His emendations and additions concern chiefly the portions on cytology, histology, embryology and palæontology, while nearly a hundred new drawings, lettered with complete words instead of abbreviations, have been inserted, or used to replace earlier figures. All this has been done without disturbance of the balance of the book.

The cytology section has been modernized; but is it not generally recognized to-day that the chromosomes persist through the resting stage of the nucleus? In the short portions of chapters devoted to embryology more recent work and better figures might have been utilized; for example, Conklin's researches on the origin and development of the mesoderm in Branchiostoma, and the interpretation of cinematograph studies of the primitive streak area in the chick.

On the whole, however, the new edition can be regarded as a most successful effort. Its bulk has been increased only slightly by the addition of about fifty pages, but the price has risen considerably. Despite the latter drawback, the book remains a rich source of information, and should prove useful to many generations of students.

N. B. EALES.

# MEDICAL RESEARCH COUNCIL UNIT FOR APPLIED PSYCHOLOGY

By DR. K. J. W. CRAIK
Director of the Unit

THE Medical Research Council Unit for Applied Psychology consists at present of eleven research workers who had previously been carrying out investigations in the Psychological Laboratory, Cambridge, principally on problems arising from the War, under the direction of Prof. F. C. Bartlett, who continues to have general supervision of the Unit. Of these, six are graduates in psychology, four in medicine and one in physiology. Until the end of the War it is likely that work of the type now in hand will continue. This has necessarily involved problems largely of an *ad hoc* character, undertaken in response to requests from Service departments, but certain common principles have emerged, which may assist in guiding a fruitful approach to future and peace-time problems. These principles are that of suiting the job to the man, of suiting the man to the job, and of improving the man's performance.

The first involves mainly the design of instruments, machinery, lay-out and illumination of maps, panels, etc. These problems may be broadly divided into those of *display* and *control*. The first term is that used by Service scientific departments to cover the methods by which information is laid visually before any operator, whether on a map, a graph, a cathode-ray tube or an instrument panel. Often the best type of display is a compromise, for example, between an instrument-panel so complex that its interpretation is slow or so simple that it gives insufficient information, or, in the case of a night-fighter aircraft panel, so brightly lit that it dazzles the pilot or so dim that it cannot be read. Psychological experiments, employing laboratory simulations of the real conditions, often enable the optimum type of display to be decided upon. Even where an optimum does not exist, a graph of the relation between, say, the distance of a plotter from a map and his accuracy in reading grid references will show a very steep rise in error beyond a certain point, and thus indicate a definite practical limit to the viewing distance, as in certain work by Dr. H. N. Mackworth. There should be a great deal of scope for such work in peace-time industrial design, especially in ensuring easier operation and preventing accidents, for example, in instrument panels, indicators, information charts and graphs. General principles have emerged which narrow the field for *ad hoc* experiments. Exact methods of scoring efficiency in war-tasks, such as watch-keeping, which are of a boring but responsible nature, have shown ways of determining optimal spells of work. The effect of discomfort, fatigue and noise on such tasks is also being studied. These techniques for the measurement of human abilities may eventually provide useful ways of assessing the progress of patients recovering from physical or mental illness, and perhaps may also test innovations introduced by researches in preventive medicine.

On the motor side, the positions, forces and gear-ratios of handles and levers on guns and machine-tools are usually compromises between the factors of speed and precision of operation, of simplicity and mechanical perfection or of psychological and physiological suitability. Here, again, particular cases are being dealt with by laboratory simulations with exact scoring of performance, and interesting principles of muscular action and sensory – motor co-ordination are emerging. These studies verge on physiology and preventive medicine.

Similar problems arise in industrial design (such as the handwheels on a machine-tool, the stage at which servo-motor or remote control becomes necessary, and the most suitable form for such control), while general principles of use to designers in less important cases could be formulated.

Any human act can be regarded as the result of a sensory – mental – motor chain of events, and hitherto those in the Unit who have worked on the above problems have concentrated rather on the sensory and motor ends of this chain, partly because of their individual aptitudes but partly, perhaps, because these are the most fruitful sites for instrumental modification. There is probably, however, an interesting future field in the analysis of the factors that make a task intellectually difficult and have led industrialists to division of labour, with its advantages of increased output and its disadvantages of boredom and discontent.

This approach—suiting the job to the man—should, we feel, be explored to the full, since it puts the industrial jobs necessary for improved standards of living within the power of the majority, whereas psychological selection alone, especially when the job has been made unnecessarily difficult, may result in a high rate of rejection and unemployment. There is, however, need for *allocation* of the available workers so that they are given tasks for which they are suited, and some selection where a task is unavoidably difficult.

This second approach—suiting the man to the job—is principally being tackled by a team under Dr. A. W. Heim. They are members of the Unit, but are working on behalf of the Industrial Health Research Board of the Medical Research Council. They have devised a battery of tests and standardized it on a large number of entrants to factories and Government training centres and some university undergraduates, and are obtaining follow-ups on the industrial subjects. This battery contains a paper test (*AH*4) consisting of a verbal and arithmetical, and a visual part based on relations of identity and opposition, analogy, completing series, and following instructions; a mechanical ability test, an inspection test consisting of metal blocks containing small defects, performance being scored on an accuracy index, speed also being recorded; some other performance tests resembling factory gauging and assembly tasks, and the National Institute of Industrial Psychology Form Relations test. The emphasis of such work must necessarily be on individual differences in ability, rather than on the features of a task which make it difficult to everyone. Research is being carried out on consistency and validity of test results and of assessments, and on the relation between these two criteria. The extent to which the value of a test depends on its degree of analogousness and the distinction between differences of *grade* and *type* of ability are also being studied.

Certain members of the Unit are investigating night vision and other tests from the point of view of selection and of diagnosing vitamin-deficiency and disease. It is hoped that there will also be some time for fundamental work on the special senses. Mr. E. Farmer has begun a study of the capacities of blinded Service personnel with the view of their obtaining suitable employment. Others are using methods which link almost equally with both the two

main approaches discussed above. For example, Miss M. D. Vernon is working on visual form perception and memory with the view both of lay-out of visual tasks and the allocation of personnel, and Dr. D. R. Davis is investigating the sensory motor co-ordination and responses of temperamentally different types of people in controlling machinery.

The third main approach is to improve the performance of the man, either by nutritional means or by mental and physical training. This, again, involves exactly controlled experimental tests of sensory and motor efficiency and scoring of performance. Various synthetic training devices have also been produced for Service use. Similar devices may well have a peace-time application, for example, to motor-car driving or machine-tool operation, where the novice is apt to injure either himself or the machine and to gain little insight into what he is doing wrong. Synthetic training equipment with exact scoring devices can assist here; but psychological experiments should always be undertaken to see whether any given trainer is in fact saving training time and improving performance, and whether it would do so equally well if it were simplified, or very much better if it were slightly complicated.

All these lines of approach involve much statistical work—for example, to establish the significance of the optimum values found for some feature of instrument design and to reveal the consistency or inconsistency of an allocation test, and its validity as judged by follow-up evidence. Though most of the members do the simpler statistical treatment of their own results, Mr. E. G. Chambers and Mr. J. W. Whitfield help in applying more complicated methods and in the development of new ones. Mr. Whitfield is also instituting a new type of recording system in a group of coal mines and two factories with the view of tracing causes of absenteeism, sickness and accidents. Such investigations indicate where there is a definite field for experimental research into improved equipment or for re-allocation or re-training of accident-prone workers.

It is hoped that there will be close contact with other bodies undertaking similar work—for example, the National Institute of Industrial Psychology—and with personnel managers, safety-officers and medical officers in factories. It must be emphasized, however, that the Unit is primarily a research body and has not the personnel or time for investigations of purely specific and local interest. Thus Dr. Heim has introduced, in several factories for which she has worked, a scheme by which members of her team inspect the problem and decide what existing test would seem appropriate and develop new ones if necessary; the firm then provides a suitable person who is trained for a fortnight or so at Cambridge, and returns to the firm to give the tests and forward the results at intervals to Cambridge. Similarly, it will be impossible to take on a large number of particular problems in display or control design; but wherever a problem of wide interest arises, or one involving test-methods which could be applied as routine elsewhere when once they have been developed, the Unit is very anxious to be of assistance to any firms who raise them; and it is hoped that similar work may continue for the Services in regard to their more fundamental problems. The essential thing is that the scientific abilities of the members for basic research which ought, sooner or later, to have its effect on particular problems, should not be swamped by work of transitory and local value.

# MODELS OF THE UNIVERSE AND COSMOLOGICAL TIME-SCALES

By DR. G. C. McVITTIE
King's College, London

THE two time-scales, one 'dynamical' and the other 'cosmological', introduced by Prof. E. A. Milne into his theory of the structure of the universe, have certain curious biological consequences pointed out in *Nature* by Prof. J. B. S. Haldane[1]. Another time-scale has just been put forward by Sir Arthur Eddington[2] on the basis of his unification of general relativity and quantum theory. It is therefore an opportune moment to attempt a general survey of cosmological investigations and, in particular, to direct attention to the very special assumptions on which the results of such inquiries depend. I do not believe that it is possible to give an accurate account of cosmological theory without expressing oneself to some extent in mathematical terms, and I trust that the reader will forgive this necessary evil—if evil it is.

## Models of the Universe

Cosmological theories, whether connected with general, or with Milne's kinematical, relativity, start from the conception of an ideal universe which we shall call a 'model of the universe'. Essentially this may be regarded as a geometrical model in which the observed aggregate of spiral nebulæ is idealized into a set of mathematical points tracing out certain curves called 'geodesics' in a 4-dimensional space-time. This space-time possesses a 'metric' of the general form

$$ds^2 = dt^2 - e^{g(t)}\left\{\frac{dr^2}{1-kr^2/R_0^2}+r^2d\theta^2+r^2\sin^2\theta d\varphi^2\right\} \quad (1)$$

Here $r$, $\theta$, $\varphi$ are space-co-ordinates, $t$ is a time-co-ordinate*, and $k$, $R_0$ are constants which, together with the undetermined function $g(t)$, we leave for later discussion, only remarking here that (1) defines not one, but a whole class, of space-time models.

To arrive at this formula we need no theory of gravitation or of dynamics: we require only the following assumptions[3]. First, the aggregate of spiral nebulæ must form a *homogeneous* aggregate, which means that the nebulæ must be uniformly distributed in space at each 'instant' $t$; secondly, each nebula must trace out a geodesic of space-time; and thirdly, these geodesics must form a 'coherent' set. The last assumption means that the aggregate of moving nebulæ is imagined as having had a continuous past history and not as having been formed by the fusion of two or more independent streams of nebulæ. In short, the metric (1) is derived from kinematic considerations together with the hypothesis of uniformity of distribution in space of the nebulæ.

Apart, however, from differences in their theories of dynamics and gravitation, general and kinematical relativity differ at this preliminary stage also. One important difference is that general relativity presupposes only that a model of the universe must possess *some metric or other*, the particular class of metrics (1) holding if it is in fact the case that the aggregate of nebulæ satisfies the homogeneity conditions set out above. If it should turn out that

* Purely as a matter of mathematical convenience, $t$ and $r$ are both measured in the astronomical unit of distance, the *parsec*, which is $3{\cdot}08 \times 10^{18}$ cm. The time in years is $t/c$, where $c$ is the velocity of light expressed in parsecs per year.

these conditions are not satisfied at present or were not true at some time in the past, general relativity would deal with the situation by discarding the models (1) and replacing them by others corresponding to the non-homogeneous conditions found to exist. Kinematical relativity, on the other hand, *postulates* homogeneity as the intrinsic character of the aggregate, and so is necessarily led to one or other of the models (1) as the only possibility. Another important difference is that, whereas in general relativity the paths of *all* material particles are by hypothesis geodesics of space-time, in kinematical relativity only the paths of the 'particles' representing the spiral nebulæ have this character. The paths of 'free' particles are curves of a more complicated type.

The uniformity postulate implies that the 'points' representing the spiral nebulæ are mathematically interchangeable with one another. It is therefore admissible to select one of them as representative, and it is usual to choose the one at the origin, $r = 0$, $\theta = 0$, $\varphi = \theta$, and to regard the nebula it represents as the typical nebula from which all the rest are being surveyed.

## Multiplicity of Models

We have already mentioned that the general considerations from which the metric (1) is derived do not define it completely, so that a wide multiplicity of models is possible. This arises, first because the function $g(t)$ is not explicitly obtained, the only restriction imposed on it being that $g(t_0) = 0$, where $t = t_0$ is the 'present moment'. Secondly, the constant $k$ can have one or other of the three values $+1$, $0$, $-1$, according as space is spherical, flat or hyperbolic, while $R_0$, the so-called 'radius of space at the time $t = t_0$', determines the scale of the model (for $k = +1$ or $-1$) and may have any positive value.

The mathematical distinction between one model and another is unfortunately not a simple one, but it is very important. The geometrical properties of the different models correspond to intrinsic differences in the velocities and accelerations of the points representing the nebulæ, in their number and their distribution in space under the general over-riding requirement that the distribution is to be homogeneous. We begin by defining the 'coefficients of the metric', namely, the factors

$$1, \quad -e^{g(t)}/(1 - kr^2/R_0^2), \quad -e^{g(t)}r^2, \quad -e^{g(t)}\,r^2 sin^2\theta,$$

which multiply the squares of the 'differentials of the co-ordinates' $dt$, $dr$, $d\theta$, $d\varphi$. A model is defined completely when the function $g(t)$ has been explicitly stated and the values of $k$ and $R_0$ assigned. For example, the choice

$$g(t) \equiv a(t - t_0), \quad k/R_0^2 = 0,$$

where $a$ is a constant, defines a 'de Sitter' universe. Now the intrinsic geometrical properties of a model depend on the coefficients of its metric, and we might therefore jump to the conclusion that models with different coefficients were necessarily intrinsically different. This, however, is not the case, because of the possibility of performing co-ordinate transformations within a given model the sole effect of which may be to alter the mathematical expression of the metric without affecting the intrinsic geometrical properties of the model. An example may make this point clearer. The ordinary 2-dimensional Euclidean plane, when expressed in terms of rectangular co-ordinates, has the metric

$$ds^2 = dx^2 + dy^2\,;$$

but it becomes

$$ds^2 = dr^2 + r^2d\theta^2,$$

when polar co-ordinates are used. In the first case, the coefficients of the metric are 1,1, in the second, 1, $r^2$. But, whichever form we use, the Euclidean geometry of the plane is the same: the three angles of a triangle sum to 180°, straight lines are of infinite length, and so on. The general mathematical problem of determining whether, of two given metrics, one can be turned into the other by a co-ordinate transformation, has not been solved in a manner which can be conveniently applied in practice. But it has been discovered that the coefficients of the metric determine a property called the 'curvature' of the model, and that the equivalence of two models depends on establishing the identity of their curvatures in a certain technical sense. A particular case of importance is that in which the curvature is identically zero, since this can be detected irrespective of the co-ordinate system used. The model of zero curvature is that of *special relativity*, the metric of which is expressible in a variety of useful forms by changing the co-ordinate system. In the customary form, we use a co-ordinate system $t_1$, $r_1$, $\theta$, $\varphi$, with the coefficients $g(t_1) \equiv 0$, $k/R_0^2$ infinite, so that

$$ds^2 = dt_1^2 - (dr_1^2 + r_1^2d\theta^2 + r_1^2sin^2\theta d\varphi^2). \qquad (2)$$

Another form which we shall need later is obtained by the co-ordinate transformation

$$t_1 = t(1 + r^2/t_0^2)^{1/2}, \quad r_1 = rt/t_0, \quad \theta = \theta, \quad \varphi = \varphi\,; \quad (3)$$

so that the metric (2) now becomes

$$ds^2 = dt^2 - \frac{t^2}{t_0^2}\left(\frac{dr^2}{1+r^2/t_0^2} + r^2d\theta^2 + r^2sin^2\theta d\varphi^2\right). \quad (4)$$

The last formula is seen to be a special case of (1) in which

$$g(t) = 2log(t/t_0), \quad k = -1, \quad R_0 = t_0, \qquad (5)$$

and serves to illustrate the point that a different choice of $g$, $k$ and $R_0$ may yet lead to the same model in two different guises. In (3) and (4) we may regard $t_0$ as the present moment in the history of the typical nebula at the origin of space co-ordinates and the co-ordinate transformation then shows that for points near this origin and for times near to $t_0$, the co-ordinates $t_1$, $t$ and $r_1$, $r$ are approximately equal.

It is essential to remember that two genuinely different models—models the curvatures of which are intrinsically different—cannot be reduced to one another by co-ordinate transformations, a point sometimes slurred over in cosmological discussions. To illustrate again from 2-dimensional geometry: the Euclidean plane with metric $ds^2 = dx^2 + dy^2$ cannot be turned into the surface of a sphere with metric $ds^2 = d\theta^2 + sin^2\,d\varphi^2$ the curvature of which is unity. This is the reflexion in differential geometry of the fact that the geometrical properties of the surface of the sphere are not the same as those of the plane, one instance of the difference being that the angles of a spherical triangle no longer sum to 180°.

## Different Time-scales

While we are still discussing co-ordinate transformations, we may mention a transformation of the time co-ordinate which plays a great part in kine-

matical relativity. It has the effect of turning the metric (1) into the form

$$ds^2 = q(\tau)\left\{d\tau^2 - \left(\frac{dr^2}{1-kr^2/R_0^2} + r^2d\theta^2 + r^2 sin^2\theta d\varphi^2\right)\right\} \quad (6)$$

The transformation is obtained by evaluating the integral in

$$\tau = A + \int e^{-\frac{1}{2}g(t)}dt, \quad (7)$$

where $A$ is an arbitrary constant, and then expressing $e^{g(t)}$ as a function of $\tau$ which we have denoted symbolically by $q$. It follows from (7) that for every choice of the function $g$ which causes the integral to 'diverge at $t = 0$', as the mathematicians would put it, the zero value of $t$ will correspond to an infinite value of $\tau$. In other words, in any such model, if the history of the universe be supposed to begin at the zero value of $t$, it will begin at an infinitely remote past time when the $\tau$ time-scale is used.

## The Red-shift

There is another result common to general and kinematical relativity which depends only on the form of the metric (1) and on the assumption that the path of a light-ray in space-time is a null-geodesic. This is that all nebulæ when viewed from the typical nebula will exhibit a displacement of the lines in their spectra either towards the red or towards the violet, according to the form of the function $g(t)$, and that there is an equilibrium model possible (the 'Einstein' universe) in which no displacement occurs. It is a matter of observation that the existing aggregate of nebulæ viewed *at the present moment* exhibits displacements to the red only. The amount of the displacement is, to a first approximation, $\frac{1}{2}g'(t_0)$ per unit of distance, the moment of observation being $t_0$ and the dash denoting the derivative of $g$ with respect to $t$. Hubble's observations[4] of the red-shift yield the numerical value[5]

$$\tfrac{1}{2}g'(t_0) = 1{\cdot}83 \times 10^{-9}\,\text{parsec}^{-1}. \quad (8)$$

We thus obtain the important result that the present-day observations of red-shift do not permit us to distinguish between one model and another: they merely provide us with an instantaneous value of the derivative of $g$ with respect to $t$.

## General Relativity and Eddington's Model

How then are we to discover the model to which the universe we see around us does, in fact, correspond? Sir Arthur Eddington's answer[2] to this question is that the combination of Einstein's gravitational equations with those of a generalized quantum theory will identify the model, and that the numerical values of any constants needed to specify it are deducible from the constants of atomic physics measured in the terrestrial laboratory.

We cannot attempt here an account of the quantum theoretical part of Eddington's theory, but we must briefly state Einstein's gravitational equations. These connect the properties of matter such as density, pressure, momentum, etc., with the curvature of the model. In the models with metric (1), it is found that the matter can have two properties only, namely, density, $\rho$, and pressure, $p$. The former is interpreted as the density of all matter contained in the nebulæ imagined as smoothed out into a uniform cloud; and the latter, as the effect of small random motions of the nebulæ and of radiation pressure. It is to be expected, therefore, that this pressure will not be sensibly different from zero, and this value is commonly assumed in cosmological investigations. The pressure and density are connected with the curvature of the model and with the celebrated cosmical constant $\lambda$ by the equations

$$\varkappa p = \lambda - 3\left(\frac{g'}{2}\right)^2 - g'' - \frac{k}{R_0^2}e^{-g} \quad (9)$$

$$\varkappa\rho = -\lambda + 3\left(\frac{g'}{2}\right)^2 + \frac{3k}{R_0^2}e^{-g}, \quad (10)$$

$\varkappa$ being proportional to the constant of gravitation $G$.

An important feature of Eddington's theory is the assumption that the expansion of the universe (manifested by the red-shift) began from a state in which the nebulæ were in equilibrium in a space of finite extent. Such a condition is found in the 'Einstein' universe the equilibrium of which, moreover, is unstable. There are models which are initially in the Einstein state but do not remain in it and start expanding instead. Eddington's model is one of these, and he can specify it completely with the help of his generalized quantum theory. His results are as follows: the model is spatially finite ($k = +1$); the total mass, $M$, of the matter it contains is also finite and fixed in amount, and the cosmical constant, $\lambda$, has the value $(\frac{1}{2}\pi c^2/\varkappa M)^2$. The radius of space, $R_0$, lies between 10 and $25 \times 10^8$ parsecs, and it is in calculating this quantity that Eddington makes one of his rare appeals to astronomical observation for an estimate of the density of matter $\rho$ in the model. The initial value of the radius is about one fifth of $R_0$. The function $g(t)$ is the simplest solution of equation (9) with $p = 0$ and is expressible in terms of logarithmic functions. But perhaps the most remarkable result of Eddington's theory is his calculation of the maximum possible value of $\frac{1}{2}g'(t)$ without appealing to astronomical observation but from the constants of atomic physics. Converting his 'speed of recession' to the units we are using, we find that $\frac{1}{2}g'(t) = 1{\cdot}91 \times 10^{-9}$ parsec$^{-1}$, which is in very remarkable agreement with the observed value (equation (8) above). Lastly, the time, on the $t$-scale, since the expansion of the model began is about $90 \times 10^9$ years. Thus, using theory together with the values of the constants of atomic physics, Eddington constructs his model, having made little or no appeal to astronomical observation in the process.

## Kinematical Relativity: Milne's Model

In contrast to general relativity, Milne does not start from the metric of the model, nor does he accept Einstein's equations (9) and (10) as defining the properties of matter in the model. But the definitions which he does use and, in particular, the requirement that all his equations shall be invariant under Lorentz transformations of the co-ordinates lead him[6] to the model (2) of special relativity and, through a co-ordinate transformation, to the form (4) of its metric. All the arguments and definitions are *a priori* and theoretical, Milne's object being to construct a model of the universe with no empirical elements.

The model of special relativity in terms of the co-ordinates $t$, $r$ (Equ. 3) has interesting properties. In the first place, 'space' is now defined as the 3-dimensional 'surfaces' $t =$ constant, and, since $k$ is equal to $-1$, it is hyperbolic and of infinite extent.

In the second place, the form of $g(t)$ is such that the zero value of $t$ corresponds to zero value for the radius of space. Physically, we should have to imagine all the nebulæ concentrated at a point with infinite density, and this is indeed the moment of Milne's 'creation'. The present radius of space, $R_0$, is identical with the age of the universe on the $t$-scale and is deducible directly from the red-shift formula (8). The radius is therefore $5 \cdot 5 \times 10^8$ parsecs, and the time since the critical moment $t = 0$ is $1 \cdot 8 \times 10^9$ years. Thus the time-scale is far shorter than in Eddington's model. The two models are, of course, not reducible to one another by a co-ordinate transformation, their curvatures being intrinsically different.

Milne's dynamical and gravitational theory is again without empirical elements, and depends on a definition of the acceleration of a free particle which makes the acceleration formula invariant under Lorentz transformations. He proves that the resulting equation of motion of the free particle can be reduced approximately to that of a particle moving under Newton's inverse square law of gravitation provided that two very remarkable conditions are fulfilled. The first condition is that the constant of gravitation, $G$, is not a constant at all but varies with the time, and the second is that the 'time' of dynamics and gravitational theory is $\tau$, whereas the 'time' of cosmological investigations is $t$ or $t_1$. This ambiguity in time-scales has hitherto escaped notice because $\tau$, $t$ and $t_1$ are all indistinguishable locally. The relation between $\tau$ and $t$ in this model is, by equations (5) and (7),

$$\tau = t_0 \log (t/t_0) + t_0,$$

the constant $A$ being adjusted so that $t = t_0$ shall correspond to $\tau = t_0$. The model, moreover, is of the kind in which the integral (7) 'diverges at $t = 0$', so that the 'time' from 'creation' is finite or infinite, according as we measure it by means of $t$ or of $\tau$, respectively. We have seen that this property is not peculiar to Milne's model but occurs in a much wider class, and is possible in general, just as much as in kinematical, relativity. It is the 'dynamical' significance attached to $\tau$ that gives this time-variable whatever importance it may possess, *not* the infinite life-time for the universe to which it leads.

Milne's model is thus an entirely theoretical structure containing one disposable constant only, $t_0$, the value of which is fixed by the red-shift observations.

## Model Deduced from Observation

We have so far discussed models arrived at in the main on *a priori* grounds. But it is also possible to treat cosmology as a branch of mathematical astronomy, and to take the appeal to observation as the important test. There is indeed a very close analogy in this respect between Newtonian planetary theory and cosmology. The former predicts on theoretical grounds that the path of a planet or comet may be an ellipse, a parabola or a hyperbola; the latter, that the observed universe may conform to one or other of a wide class of models. It is not regarded as satisfactory to announce *a priori* that the orbit of a newly discovered comet must be an ellipse, for example, and to disregard the observations of its path however few and inaccurate they may be. Yet such an attitude is not uncommon among cosmologists.

Pursuing this possibly old-fashioned and certainly unpopular line of thought, I have tried to identify the model to which the universe conforms by using astronomical observations combined with Einstein's gravitational equations ((9) and (10) above). We have the following observations at our disposal: measurements of the red-shift, estimates of the number of nebulæ per unit volume and of the mass of an average nebula; and, most important of all, observations[4] of the distribution of nebulæ 'in depth'. These give the average number of nebulæ per unit area of sky at successively fainter apparent magnitudes. None of these observations are either so accurate or so complete as they might be, but the important point is that they *do* give a solution of the cosmological problem. In reaching it, I discarded Hubble's method of applying *a priori* 'corrections' to the observations, since I was able to show that one at least of these corrections was equivalent to imposing an unacceptable restriction on the function $g$. Hubble[4], indeed, had arrived at a model in which space was finite ($k = +1$) but of such small extent that he rejected the interpretation of the observations by means of *any* of the models (1) in favour of an account in terms of the loss of energy of light-radiation as it traversed space. Nevertheless, taking Hubble's observational figures without applying 'corrections', I was able to show[5] that they led to a model with the specifications: $k = -1$, $R_0 = 4 \cdot 515 \times 10^8$ parsecs, $\lambda = -0 \cdot 050 \times 10^{-16}$ parsec$^{-2}$. The function $g(t)$ is a solution of the equation (9) with $p = 0$ expressible as an elliptic function. The model, therefore, has hyperbolic space, which is of infinite extent, and the expansion begins at $t = 0$ from an infinitely concentrated state as in Milne's model. The function $g$ is of the kind for which the integral in (7) does not diverge at $t = 0$, so that the life-history of the model is finite, whichever time-scale we use. On the $t$-scale it amounts to $1 \cdot 5 \times 10^9$ years. The curvature of the model is intrinsically different from that of Eddington's or Milne's, so that it cannot be transformed into either of them by co-ordinate transformations. No doubt more accurate observations will, in the future, alter the model, just as the orbit of a comet is perhaps found to be a parabola on the basis of the first available observations of its path but later turns out to be an ellipse as more numerous and accurate measurements accumulate.

In deriving this model, I made use of Einstein's equations, which do not apply in Milne's theory. But using the equations which take their place in kinematical relativity, I have not succeeded[7] in reconciling the predicted and the empirical formulæ for the distribution of nebulæ in depth to the same degree of accuracy as is possible in general relativity.

## Conclusion

We are thus presented with three different models of the universe, two of which are based essentially on theory whereas the third is derived by the maximum of appeal to observation. Eddington's model implies a time-scale some fifty to sixty times longer than the time-scales of the other two. Milne, however, gives a physical interpretation to a second time co-ordinate in terms of which the universe has an infinite life-time. All three models imply that the universe began expanding from somewhat peculiar initial conditions: Eddington's from a state of unstable equilibrium; the other two, from 'explosions' at a point. The calculated time-scales are measured from these initial states and are therefore dependent

on the assumption that the roughly homogeneous conditions observed at the present day have persisted through the past history of the universe. It is scarcely necessary to emphasize the speculative and provisional nature of such extensive extrapolation.

# OBITUARIES

## Prof. G. F. Stout

BY the death in Sydney of Prof. G. F. Stout, emeritus professor of logic and metaphysics in the University of St. Andrews, at the age of eighty-four, British philosophy and psychology have lost one of its most representative and distinguished figures. A first class in the Classical Tripos in Cambridge in 1882, followed in the next year by a first in the Moral Sciences Tripos, seem, on the face of it, strange preparation for a man who was to become a dominant figure in British psychology for the next two generations, and who, as late as 1936, after fifty years of academic life, could enter into equal fray with the new *Gestalt* experimental psychologists from Germany. But three further factors must be taken into account: the presence of Ward at Cambridge, the nature of British philosophy and Stout's own penetrating insight. That Ward was one of the dominating influences in his life, Stout himself was ever ready to admit. Ward's article on psychology, in the "Encyclopædia Britannica" of 1885, ultimately embodied in his "Psychological Principles", was the precursor of Stout's "Analytic Psychology" (1896) and his "Manual of Psychology" (1898), and both these latter books bear the marks of this influence. But both Ward and Stout were following in the clearly marked tradition of British psychologists and philosophers from the seventeenth century onwards, and Stout himself was, until his death, the ablest survivor of a type of philosophy which included Locke, Hume, the two Mills and the Scottish school.

Neither Ward nor British tradition, however, can account for the fact that a text-book on psychology written nearly fifty years ago is still, despite the many changes in technique and outlook, an indispensable work for teachers and students alike. Here two points call for comment. The first was Stout's superb intellect, with its keen insight into philosophical and psychological problems, and the second, his freshness of mind, which never lost its interest in his subject and enabled him to revise one edition after another.

Stout left Cambridge in 1897 and was for two years lecturer in Aberdeen in comparative psychology and for four years Wilde reader in mental philosophy at Oxford. In 1903 he was appointed to the chair at St. Andrews. From this period his writings were, in the main, on epistemology and metaphysics. In the former, the influence of Plato, and particularly the Theatetus and Sophist, is obvious; in the latter, his animism and his views on the body and mind are Spinozistic. But Stout was never merely a copy of any other thinker; his originality was too strong for that: and for this same reason, although his knowledge of philosophical literature was astounding, he was not a mere scholar. He was a thinker first and always, and in his reading he both re-thought and re-moulded. It is not possible in a short notice to go into details of Stout's philosophy, but I hazard the opinion that if readers of *Nature* would ponder the Gifford Lectures (Stout, "Mind and Matter", 1931) of a former editor of *Mind* (Stout edited *Mind* from 1891 until 1920) British scientific philosophy would be a far better thing than it is at present.

To the bulk of St. Andrews students—Stout, in the main, lectured only to a small number of advanced students—and to most members of the staff he was a mythical figure, spoken of with awe and around whom legends and anecdotes were spun of a recluse living in a rarified atmosphere of pure thought. Those of us who worked with him and who talked and walked with him for many years knew what a caricature this was. In addition to his extensive knowledge of philosophical and psychological literature, Stout was one of the best read men of a reading generation, in literature, history and in many branches of science, and his judgment of men and affairs was unerring. He seemed to have read (and to remember) everything, and he showed the same penetrating insight in his judgment on affairs that characterized his professional work. Those who only know the latter never really knew Stout, who will always be remembered by his friends as a man who not only gained the highest distinction in his own branch of study but who had also assimilated the matter and spirit of European culture from the Greeks downwards. Even among academics he was an aristocrat. We of a later generation knew that, as did men like Ward and Bradley of his own. J. N. WRIGHT.

## Dr. E. N. Miles Thomas

WITH the death of Dr. E. N. Miles Thomas on August 8, there passed one of the most brilliant women botanists of the century. Educated at the Mays High School (Home and Colonial School Society), she studied also at University College, London (where she was later made a fellow) and at the Imperial College of Science and Technology. Her contact with Miss Ethel Sargent, to whom she acted as research assistant (1897–1901), and with Mr. (later Prof.) A. G. Tansley was probably responsible for her life-long devotion to problems of seedling anatomy.

Her appointment as lecturer at Bedford College in 1908 marked the inauguration there of a separate Botanical Department, and in 1912, she was also awarded the status of reader in the University of London. The Department made rapid progress under her vigorous leadership and was already well established in the new premises of the College in Regent's Park when war broke out in 1914. Like others, Dr. Thomas felt the urgency of war claims, and when her appointment terminated in 1916 she became an inspector of the Women's Land Army for London and the Home Counties. Afterwards she became acting head of the Botanical Department in University College, Cardiff, during 1918–19 and keeper of the Department of Botany in the National Museum of Wales during 1919–21. In 1923, she was appointed lecturer in biology at University College, Leicester,

a position which she held until her retirement in 1937. Her activities in these various spheres were tireless, but as a life member of the British Association for the Advancement of Science, she also took part in many of the meetings, including those of Australia (1914), Canada (1924), and South Africa (1929); also acting as recorder (1920, 1921) and vice-president (1933) to Section K. She was elected fellow of the Linnean Society in 1908 and served on the Council during 1910–15. She was deeply interested in questions affecting the professional status of women workers. She also tried to promote the formation of a central botanical research institute; but the funds collected were insufficient and were used in furtherance of research by other means. She had friends in many lands, and in 1924 served, appropriately, on the executive committee of the Imperial Botanical Conference.

Dr. Thomas's published work included double fertilization (*Ann. Bot.*, **14**; 1900); anatomy of *Acrostichum* (*New Phyt.*, **4**; 1905) and a series of articles on seedling anatomy, reinforced by those of some of her students. Her name is especially associated with the theory of the double leaf-trace (*New Phyt.*, **6**; 1907); but the trend of her views on more general questions of seedling anatomy is clearly indicated by a series of summaries (British Association Reports for 1906, 1914, 1923 and 1924) as well as by longer articles (*Ann. Bot.*, 1914; *Proc. Linn. Soc.*, 1923). She had hoped to develop these researches further, but failing health and other circumstances prevented her from bringing her work to full fruition. On her breakdown in 1940, her slides, records, etc., were catalogued and placed in the Jodrell Laboratory, Kew. She was married to Mr. H. H. F. Hyndman, but his sudden death in 1934 brought to an untimely end a particularly happy union. The shock, though faced with characteristic courage, was undoubtedly one of the causes precipitating her final breakdown.

# NEWS and VIEWS

## British Non-Ferrous Metals Research Association: Retirement of Dr. Harold Moore, C.B.E.

DR. HAROLD MOORE, who will retire from the position of director of the British Non-Ferrous Metals Research Association on October 31, has occupied that position for the last twelve years. Dr. Moore is a native of Middlesbrough, and received his metallurgical training from the late Dr. J. E. Stead, taking a London degree. After two years in a Northamptonshire blast-furnace works he joined Messrs. Beardmore at their Parkhead works, where he was engaged on problems of armour-plate manufacture. In 1904 he became chief metallurgist in the Research Department, Woolwich, being given the title of Director of Metallurgical Research in 1919. Besides controlling a staff engaged in research on armaments, he did valuable work on the development and interpretation of the hardness test, and in collaboration with S. Beckinsale published an important investigation on the season cracking of brass, work which arose out of difficulties with cartridge cases, but was the starting point of a study which has been actively taken up by others.

Dr. Moore was awarded the C.B.E. in 1932, in which year he was appointed to succeed Dr. R. S. Hutton as director of the British Non-Ferrous Metals Research Association. During his tenure of the directorship the equipment and staff of the laboratories in Euston Street have grown considerably, and many investigations of great value to the non-ferrous metals industry have been carried out. Dr. Moore has from the beginning taken an active part in the work of the Institute of Metals, of which he was president during 1934–36. In 1943 he received the Platinum Medal of the Institute. He has also served on many councils and committees concerned with metallurgy. In all these capacities his personal qualities have contributed largely to the smooth working of research organizations.

## Royal Holloway College: Chair of Mathematics

THE chair of mathematics at the Royal Holloway College, vacant through the resignation of Prof. Bevan Baker, has been filled by the appointment of Prof. W. H. McCrea. Since 1936 Prof. McCrea has been professor of mathematics at the Queen's University, Belfast, but for some time has been on leave in London on war service. Prof. McCrea had previously been an appointed teacher in the University of London, while holding an assistant professorship at the Imperial College during 1932–36, and during that time he took an active part in the scientific life of London, particularly in connexion with the Royal Astronomical Society. In addition to being an excellent teacher to university students over a wide range of mathematical ability and interest, his scope as a researcher is unusually extensive. He is specially distinguished for his researches in astrophysics, to which he has contributed many fertile ideas. His theory of the solar chromosphere, modifying an earlier theory by Prof. E. A. Milne which attributed the main support to selective radiation pressure, is generally accepted, and includes pioneer work that first showed the importance of turbulence for the structure of the sun's atmosphere. He also constructed a model of a stellar atmosphere based solely on physical as distinct from astronomical data, thereby initiating a method of investigation afterwards widely followed. Among his other astrophysical researches are a theory of the ejection of matter from 'new' stars (novæ), and a study of the drag of one gas on another through which it is streaming. Prof. McCrea has also shown marked originality in other fields, which include the quantum theory of specific heats and of quadrupole radiation, cosmological relativity theory, wave-tensor calculus, and differential and difference equations.

## New Chair of Geography at McGill University

MR. GEORGE H. T. KIMBLE has been appointed first professor of geography and head of the newly created Department of Geography in McGill University. Until the outbreak of the War, when he volunteered for the Naval Meteorological Service, Mr. Kimble was lecturer in geography in the University of Reading. He took his bachelor's and master's degrees at King's College, London, during 1927–31, where he studied under Prof. Ll. Rodwell Jones and the late Prof. A. P. Newton, and did his early work in historical geography. The results, so far published,

of these researches are contained in "Geography in the Middle Ages" (Methuen, 1938), in a memoir accompanying the Royal Geographical Society's reproduction of "The Catalan World Map of the R. Biblioteca Estense at Modena" (1934), and in a critical edition of Pacheco's "Esmeraldo de Situ Orbis", published by the Hakluyt Society (1937). On the human side he has made a number of studies of marginal environments and economies, notably of the Berbers of the Algerian Atlas (*Geog. J.*, 1941), and shortly before the War he wrote a popular introduction to the subject called "The World's Open Spaces" for Nelson's Discussion Series. The preoccupations of the past five years may be held to explain the temporary diversion of his interests as revealed in his most recent publications, namely, "The Shepherd of Banbury's Rules for Telling the Weather" (University of Reading, 1941) and "The Weather" (with Raymond Bush) published by Penguin Books in 1943. Mr. Kimble hopes to take up his new appointment in January 1945.

### Pulkovo Observatory Library

ALTHOUGH information had been received that the most valuable of the instruments had been removed from the Pulkovo Observatory before it was shelled and bombed by the Germans, there had been no news about its valuable library, which contained many rare treasures, including the manuscripts of Kepler. It is now learned from the *Moscow News* that the library had remained in the building, stored away in the basements. After the Observatory had been shelled for three weeks, it was decided to save the library at any cost. In the middle of October 1941, under incessant German artillery fire, the removal of the library was undertaken by the employees of the Leningrad Museums and Park Administration. Truck after truck pulled up to Pulkovo until all the books had been removed. The Observatory is now a mass of ruins, but the Academy of Sciences of the U.S.S.R. has been instructed by the Government to draw up and present by November 1 a project for the rehabilitation of the Observatory.

### Illuminating Engineering Society

THE presidential address delivered by Mr. E. Stroud at the opening meeting of the Illuminating Engineering Society on October 10 took the form of a survey of the Society's activities and its future. The Society was formed by Mr. Leon Gaster in 1909 and its first president was Prof. Silvanus P. Thompson. At that time there was little information in regard to lighting practice, and the instruments available for the measurement of illumination were few and cumbersome. Much original work was done by Mr. A. P. Trotter and other early pioneers to deal with the lighting of schools and libraries and other subjects. The setting up of the Home Office Committee on Factory Lighting in 1913 was an important landmark. During the War of 1914–18 members of the Society did useful work on the measurement of the candle-power of flares and the brightness of radium compounds for coating gunsights, etc., and the year 1915 saw the issue of the first of the series of reports on factory lighting issued by the Departmental Committee. During the first twenty years the foundations of the Society were laid. The floodlighting of London buildings, which accompanied the holding of the International Illumination Congress in London in 1931, did much to direct attention to its work. Efforts were made to create interest in the provinces, where the first centre, in Manchester, was formed in 1932.

From 1934 onwards there ensued a period of development. The membership, at this time about 450, advanced to 850 at the commencement of the present War, and has now reached more than 1,600 —nearly a fourfold increase during these ten years. Several ambitions of the Society have since been realized, such as the formation of the nucleus of a library, the issue of *Transactions* and the establishment of a class of fellowship. This present growth of membership has been mainly due to the development of centres, now ten in number, with which, and with five supplementary groups, there are associated more than a thousand members. The growing recognition of the importance of good lighting is illustrated by the official recognition given to the I.E.S. Code of values of illumination. The inclusion of lighting in the Factory Act of 1937 makes good an omission stressed by Prof. Silvanus Thompson in his inaugural address thirty-five years ago. During the present War the Society has devoted much attention to A.R.P. lighting problems. A series of "Lighting Reconstruction" pamphlets has also been issued. There are various plans in preparation, such as those relating to the education of lighting engineers. In years to come there should be great opportunities for lighting. Closer links should be established with the sister societies in the United States and the Dominions, and international contact should be revived.

### Dried Plasma Sheets for Burns and War Wounds

"IT has often been said," remarks Lieut.-Colonel B. Pollock, U.S.N.R. (*U.S. Naval Bull.*, 42, 1171; 1944), "that this is a burn war." The incidence of burns has greatly increased, and there is urgent need of an ideal coagulum for them. Such a coagulum should be durable, non-contractile, indefinitely pliable, non-toxic, non-irritant, resistant to trauma, bactericidal, painless, not unsightly, and it should contain fibrin and not be costly to make. Dried plasma sheets apparently come closer, he thinks, to these requirements than any other coagulum yet introduced. Dried plasma dissolved in water and dried in a hot oven gives a transparent, slightly elastic, adherent coagulum, and the addition of sulphanilamide or sulphathiazole increases its bactericidal effect. These substances are slowly liberated as the fibrin is used up, and they thus keep the wound clean.

The sheets are made in a Petri dish to a size of 4 in. in diameter. 20 c.c. of sterile water is put in the Petri dish and 1·5–2 gm. of dried plasma added. After this has dissolved 0·2 gm. of sulphanilamide powder is added. This is then dried in an oven at 140° C. until a sheet is formed. This requires 15–20 minutes. After cooling, the sheet should be applied directly to the burn. Sheets can be quickly made by heating the preparation over a Bunsen burner until the sheet separates itself in less than five minutes. The addition of more or less water or plasma thickens or thins the sheet. Its transparency increases or decreases according to the amount of sulphanilamide added. If the preparation is dried for only ten minutes, it forms a paste which is also useful. The sheets tend to curl at the edges as skin does, but this can be overcome by moistening them with water before application. They adhere to a

burn in a few moments and the patient may feel a burning or stinging sensation for one or two or possibly thirty minutes. No dressing is needed. The sheets will adhere to the unbroken skin. They can be kept for weeks if they are moist in a refrigerator; or they may be heated until they are crisp and dry, when they may be stored in a refrigerator. The sheets gave good results when they were applied to indolent, ulcerating war wounds, all of which were infected. Wounds still unhealed after sixty days of other treatment healed in six to nine days. Tissue reactions subsided forty-eight hours after their application. None of the patients was confined to bed and some had shower baths without protection of the plasma sheet. Dry dressings were used at night only.

## Taxation and the Social Structure

THE papers presented before the American Philosophical Society in the symposium on "Taxation and the Social Structure" at its midwinter meeting on February 18–19, 1944, have now been published (*Proc. Amer. Phil. Soc.*, 88, No. 1, 1; 1944). American conditions, with the complex relations between State and Federal taxation, to which there is no exact parallel in Great Britain, make the papers somewhat difficult for British readers to follow. Nevertheless, they are of interest at present in view of the reconsideration of the relations between national and local taxation which is being enforced upon Great Britain by some of the trends towards social security, and also of the bearing of fiscal policy on industrial development, such as the concessions announced by the Chancellor of the Exchequer in relation to obsolescence and research in his last budget speech. In Britain, as in the United States, it is realized that taxation is no passive instrument, but that it inevitably affects the social structure and determines the course of social evolution. Accordingly, taxation policy is an integral part of general social and economic policy, and as such must be recognized in our social philosophy.

Four at least of the papers in this symposium make some contribution to this end, and have a much wider bearing than the issues of Federal and State taxation to which the principles they develop are applied. R. Warren's paper on "The Capitalist and the Social Structure", R. Blough's "Conflict and Harmony in Taxation", H. S. Bloch's "Fiscal Policy and Social Reform as it may affect the Potentialities of the Personal Income Tax", and M. H. Hunter's "The Harmonisation of Fiscal and Social Aims" should make important contributions to clear thinking on these problems. Blough's paper in particular is a challenge to fundamental thought and a plea for further research on the relation of taxation to production and employment.

## Potato Varieties in East Africa

THE problem of potato varieties suitable for East Africa is discussed by R. E. Moreau, of the Amani Research Institute, in the *East African Agricultural Journal*, 9 (1944). The inquiry was concerned with the direct physiological effects of climate on the plant and should give some guide to policy when the desired development of the crop is undertaken. The generally accepted view that *Solanum tuberosum* is an unsuitable crop for hot climates is called in question and the conclusion reached that, given good husbandry, excellent crops of it can be raised in parts of tropical Africa, even though air and soil temperatures seem unfavourably high. The short days appear to be of no practical importance, and it is suggested that there may be some countervailing influence in the tropics, such as increased light intensity which accounts for this. The possibility that potatoes of the *Solanum andigenum* group would do better than United Kingdom varieties of *S. tuberosum* is dismissed on purely climatic grounds, though an exception is made of *S. phureja*, which has the further advantage of possessing a particularly high protein content. It is, however, suggested that United States varieties of *S. tuberosum* merit special trial on the score of their possible better adaptation to heat.

## Public Health in Haiti

IN a recent paper (*Bol. Of. San. Panamericana*, 23, 299; 1944) Dr. Jules Thebaud, director-general of public health in Haiti, states that the public health department in his country employs 542 persons, exclusive of day labourers. Owing to lack of funds, Haiti has hitherto been unable to keep pace in public health works; but it has endeavoured to maintain close relations with the Pan-American Sanitary Office. The population of Haiti is estimated at 3,000,000; in 1942 there were 44,805 births, 12,416 deaths and 3,298 marriages. The principal causes of death in 1942 were contagious and parasitic diseases (25·9 per cent), digestive diseases (14·6 per cent), genito-urinary diseases (6·8 per cent) and respiratory diseases, except tuberculosis (6·1 per cent).

## Announcements

THE Lord President of the Council has appointed Mr. W. J. Drummond, Dr. H. L. Guy, Sir William Halcrow and Mr. W. F. Lutyens to be members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, in succession to Sir Joseph Barcroft, Sir Harold Hartley and Sir Frank Smith, who have retired from the Council on completion of their terms of office.

LORD SWINTON, minister resident in West Africa, has been appointed Minister for Civil Aviation, and Sir William Jowitt to be Minister of Social Insurance (designate).

DR. HARLOW SHAPLEY, director of Harvard Observatory, has been awarded the Order of the Aztec Eagle, third class, the highest decoration of the Mexican Government awarded to non-Mexicans, for his promotion of scientific co-operation between the United States and Mexico, and for his assistance in equipping the National Astrophysical Observatory at Tonanzintla, near Puebla, Mexico.

THE forty-ninth annual congress of the South-Eastern Union of Scientific Societies is being held at High Wycombe on October 14. The president-elect, Brigadier F. A. E. Crew, director of biological research at the War Office and professor of social medicine in the University of Edinburgh, will deliver his presidential address on "The Biology of War" at 11 a.m.; sectional presidential addresses will precede this address.

ERRATUM.—Messrs. Baird and Tatlock (London), Ltd., referring to the paragraph entitled "A New Type of Still" in *Nature* of September 23, p. 393, state that in line 15 "motor" should read "heater", and that the results quoted are the average of a number of experiments.

## Nutritive Value of Composite Dishes

IN McCance and Widdowson's analytical tables, "Chemical Composition of Foods", values are given for a series of cooked dishes containing several ingredients. These values were calculated from the composition of the listed ingredients and the (experimentally determined) change in weight on cooking.

Clearly, such values can only be utilized in dietary survey work if the recipes of the observed composite dishes approximate very closely to those used by McCance and Widdowson. These authors made a preliminary study of several cookery books so as to ensure that the recipes they used should be 'standard' ones. But the war situation has since changed our ideas even of 'standard recipes', and composite dishes tend to vary from day to day, depending on what is available and what needs using up. Besides which, the composition of one of the most common ingredients (flour) has itself been changed.

It is true that there are limits to the variation which can be introduced without entirely altering the nature of the finished dish, but our experience suggests that, at least for the more watery items, these limits are pretty wide. The accompanying table gives values we have found in practice.

| Values per 100 gm. | Calories | Protein (gm.) | Calcium (mgm.) | Iron (mgm.) |
|---|---|---|---|---|
| Rice pudding 1 | 158 | 4·9 | 138 | 0·17 |
| ,, ,, 2 | 183 | 4·8 | 129 | 0·17 |
| ,, ,, 3 | 88 | 2·7 | 81 | 0·09 |
| ,, ,, 4 | 97 | 2·6 | 73 | 0·09 |
| (McC. and W.) | 185 | 4·5 | 138 | 0·14 |
| Porridge 1 | 66 | 1·7 | 33 | 0·29 |
| ,, 2 | 91 | 2·9 | 53 | 0·54 |
| ,, 3 | 117 | 3·4 | 62 | 0·63 |
| ,, 4 | 135 | 4·0 | 46 | 0·99 |
| (McC. and W.) | 45 | 1·5 | 6 | 0·47 |
| Stew with meat 1 | 103 | 9·2 | 21 | 1·81 |
| ,, ,, ,, 2 | 101 | 8·0 | 23 | 1·57 |
| ,, ,, ,, 3 | 89 | 3·5 | 8 | 0·96 |
| ,, ,, ,, 4 | 97 | 7·3 | 31 | 1·48 |
| ,, ,, ,, 5 | 61 | 6·0 | 15 | 1·23 |
| (McC. and W.) | 108 | 11·1 | 14 | 2·49 |
| Shepherd's pie 1 | 165 | 8·3 | 6 | 1·72 |
| ,, ,, 2 | 149 | 7·8 | 17 | 1·61 |
| ,, ,, 3 | 139 | 8·0 | 13 | 1·67 |
| (McC. and W.) | 125 | 7·1 | 15 | 2·31 |

These values have been obtained by the calculation method as employed by McCance and Widdowson, and the figures from their tables have been included for comparison.

Our method, when dealing with composite dishes in survey analyses, has always been to obtain the recipes and to note the cooking times and methods, and then to apply a concentration factor to give us the relation between uncooked weight and cooked. Recorded weights (as eaten) were then converted back to their equivalent uncooked weights and these broken down into the proportional weights of the various ingredients. As a general rule, the concentration factor applied was that found by McCance and Widdowson, but if observation showed the dish as served to be wetter or drier than is customary, then the concentration factor was varied accordingly.

We prefer this method because we think it makes for greater accuracy. Concentration factors may have differed more than we allowed for, but we feel they will certainly vary within much narrower limits than the list and amounts of the ingredients. There are, however, other advantages also. For example, it enabled us to make direct comparison between one intake and another in terms of basic foodstuffs, since they were known as a total and were not distributed among such items as puddings, stews, cakes, etc. It is easier to make recommendations for improving a dietary when the amounts of different foodstuffs already being used are known. This is particularly true at present when it is necessary to keep within allocated allowances. Moreover, this method enables us to calculate the cost of the dietary without further detailed analysis.

## Cancer Research in the U.S.S.R.

IN November last we received a request from Prof. S. A. Sarkisov of the Institute of the Brain in Moscow, who was then in London, to supply some mice bearing transplantable tumours which were to be sent to Moscow for Prof. L. Shabad, formerly director of the Laboratory of Cancer Research in the Institute of Experimental Medicine, Leningrad.

The mice were to be sent by air, and probably they would be exposed to considerable changes of climate, and possibly of atmospheric pressure also. Three batches each of four mice were got ready bearing the following tumours freshly grafted: (*a*) mammary carcinoma 63; (*b*) the Crocker tumour; and (*c*) a sarcoma induced here by Dr. Hieger with the non-saponifiable fraction of human livers. The inclusion of the last tumour was appropriate because these mice embodied a development of the original discovery by Prof. Shabad in 1937, since then confirmed in several other laboratories, that extracts of human livers could produce sarcoma in mice.

Each batch of mice was placed in a wooden box (45 cm. × 30 cm. × 12 cm.) having three apertures of 5 cm. diameter covered with perforated zinc for ventilation, with hay and sawdust as bedding, and a quantity of oats, puppy biscuits and a proprietary rat food sufficient for many weeks. Water was supplied from the bulbs in use here for laboratory animals, and a syringe for filling these and directions to be translated into Russian were provided. The boxes were dispatched on November 23, and Prof. Shabad has reported that all the mice arrived safely in mid-December, and that the three tumours had been grafted successfully in the mice available in his laboratory.

Perhaps this is the longest journey yet accomplished by mice used for the purposes of research; the distance covered was probably of the order of five or six thousand miles. Before the War many such mice crossed the Atlantic on liners, chiefly from west to east, in charge of the butcher, who at sea is the custodian of animals living and dead, but this is a shorter journey without halts and changes, and the conditions of temperature are uniform.

## Amides, Imides and Peptides

PROTEIN chemistry has its origins in physiology. For the last half-century the group formed by condensing the carboxyl group of an amino-acid with the amino group of another amino-acid has been called a peptide group, and the long molecule formed by condensing a number of amino-acids, a polypeptide. Protein molecules contain numerous peptide links (—CO.NH—) in the backbone of the molecule; they also in most cases carry amido groups (—$CO.NH_2$) as terminal groups of certain of their side-chains.

'Nylon' chemistry has its origins in organic chemistry. Unfortunately, some 'Nylon' chemists have chosen to call the link formed by condensing adipic acids with hexamethylene diamine an 'amide group', and to describe 'Nylon' as a 'polyamide'. 'Nylon' chemistry is now beginning to have an influence on protein chemistry, and the use of the term 'amide' as a synonym for 'peptide' in a field of chemistry where it already has a definite and different meaning is causing considerable confusion.

Surely, in any event, to call the group —CO.NH— an 'amide' or even an 'amido' group is wrong. By general agreement substances carrying an —$NH_2$ group are amines, or an >NH group, are imines. Equally, substances carrying a —$CO.NH_2$ group are amides, and surely if carrying a —CO.NH— group should be imides.

To use the term 'imide' as a synonym for 'peptide' and to call 'Nylon' a polyimide would be correct in the language of classical organic chemistry, and would bring clarity into the relations of protein chemists and 'Nylon' chemists. 'Polypeptide' could well be reserved as a term to describe a product obtained by condensing amino-acids, and 'polyimide' for the products obtained by condensing all other carboxylic acids with organic amines.

## Chemical Terms, with Special Reference to 'Oxidation', 'Acid' and 'Base'

THE words we use in everyday life often mislead us, because the same word (say 'democracy') means different things to different people. It is clearly desirable that scientific words should mean the same thing to all those who use them, and, so far as possible, that they should signify now what they signified in the past.

We say "so far as possible". When the mechanism of a process, such as the corrosion of iron, becomes better understood, the word 'corrosion' acquires a fuller meaning. This is inevitable and desirable. It would be undesirable, however, in our view, if a particular reaction of iron were considered a corrosion by one chemist and not by another.

There is a tendency to extend the scope of a word to include phenomena which were formerly excluded. This has happened in the past; for example, in the case of the word 'oxidation'. The term, originally applied to processes such as the change of ferrous oxide to ferric oxide, was extended to include the change of ferrous chloride to ferric chloride. This extension took place so long ago that it causes confusion now to none except beginners (to whom it is still a stumbling-block), and it would probably be futile to suggest a change. It seems to us, however, that it would have been better, when it was realized that there was a similarity between oxidations proper and other processes in which the proportion of electronegative element or radical is increased, to coin a new term (say, 'adduction') to cover both sets of phenomena, while keeping 'oxidation' for changes involving oxygen. All 'hydrogenations' are 'reductions', but not all 'reductions' are 'hydrogenations'.

It is impossible to extend the scope of a word to include more phenomena without diminishing its sharpness. In the language of the logicians, increase in the extension of a term leads inevitably to decrease in its intension. The term 'oxidation' now conveys a less precise meaning than 'hydrogenation'.

If this were the only example of the phenomenon it would not be worth while writing a letter about it; unfortunately the process is still at work. There was little disagreement among early chemists about the scope of the words 'acid' and 'base'. When hydrogen ions were discovered the words acquired a fuller meaning, but were still applied to cover approximately the same range of substances.

In the last twenty years, however, the recognition that there is a similarity of action between all substances capable of giving up protons or taking up electrons during reaction has led to the extension of the term 'acid' to include all such, and we have now reached the very undesirable position that, while $A$ and $B$ are agreed that hydrochloric acid in aqueous solution is an acid, $A$ applies the word to $NH_4^{\cdot}$ and water also, while $B$ thinks of $NH_4^{\cdot}$ as the electropositive ion of an important series of salts and of water as the most typically neutral substance in existence.

In a recent paper[1] the following sentence occurs, "We conclude that almost any substance may behave as an acid or a base". The extension of 'acid' and 'base' has become so great that the intension has become practically nothing at all.

We think it is probable that a majority of chemists feel uncomfortable at the application of the term 'acid' to water or 'base' to the chloride ion. Perhaps it is not too late to recognize the undesirability of the process and to agree upon the use of some pair of terms (such as 'proton donor' and 'proton acceptor', or 'electrophilic' and 'electrodotic', or others suggested from time to time) to describe all substances (including acids and bases) which can give up or receive protons (or attract or supply electrons), while preserving 'acid' and 'base' for the compounds which have been described by these words for centuries.

## Thermal Expansion of Diamond

THE measurements of the thermal expansion of diamond made by Dembowska, which according to Grüneisen[1] appeared to support his well-known formula connecting the specific heat and thermal expansion coefficient of simple solids, covered only

a rather small range of temperature. A satisfactory test of the Grüneisen relationship appeared to require data over a wider range of temperature. I have accordingly measured the change in the lattice spacing of diamond with temperature over the range 25°–650° C.

The X-ray method has been employed, but the technique is rather different from that usually adopted, being designed to enable the rather small expansion of diamond to be measured accurately. It is based on the use of a beam of monochromatic X-rays from a copper target diverging from a fine slit and reflected at the surface of the crystal, the photographic film recording the reflexions being at a considerable distance (80 cm.) from the latter. The octahedral cleavage plate employed is held firmly in a slot at the end of a drawn-out tube of fused quartz, being fixed therein with a suitable cement. The quartz tube is long enough to ensure that its lower end is not sensibly heated up, while the diamond itself is raised to the temperature desired by being enclosed in a small electrically heated chamber. Using a Hartmann diaphragm, three sets of X-ray reflexions are recorded in juxtaposition on the same film, the middle one with the heated crystal and the top and bottom ones as controls at room temperature. From the observed displacements of the $K\alpha_1$ and $K\alpha_2$ reflexions, which appear as sharp and widely separated lines on the film, the relative change in crystal spacing can be readily evaluated. As a further control, the expansions are redetermined with the crystal holder and heating chamber turned round through twice the Bragg angle.

The results of the measurements are shown in the second column of the accompanying table below the line, those above it being the determinations by Dembowska quoted by Grüneisen[1]. The values of the atomic heat have been tabulated from the data of Pitzer[2] below 273° K. and from the data of Magnus and Hodler[3] above that temperature.

| Temperature range | Mean value of the coefficient of cubic expansion ($\alpha$) | Mean value of atomic heat ($C_v$) | $\gamma$ |
|---|---|---|---|
| 84·8–194·1° K. | 0·54 × $10^{-6}$ | 0·233 | 1·19 |
| 194·1–273·2 | 1·74 | 0·866 | 1·03 |
| 273·2–296·2 | 2·91 | 1·351 | 1·10 |
| 296·2–328·1 | 3·51 | 1·605 | 1·12 |
| 328·1–351·1 | 4·35 | 1·870 | 1·19 |
| 298–378 °K. | 4·50 × $10^{-6}$ | 1·870 | 1·23 |
| 378–478 | 6·70 | 2·627 | 1·31 |
| 478–573 | 8·58 | 3·307 | 1·32 |
| 573–673 | 9·81 | 3·874 | 1·30 |
| 673–773 | 10·70 | 4·310 | 1·29 |
| 773–873 | 11·55 | 4·643 | 1·27 |
| 873–923 | 12·30 | 4·829 | 1·30 |

The fourth column of the table shows the Grüneisen number $\gamma$, which is the ratio $\alpha V_0/\chi_0 . C_v$, where $V_0$ is the atomic volume and $\chi_0$ the compressibility of diamond. It is clear that $\gamma$ is not a constant, but increases steadily from about 1·1 to 1·32 and then falls again as the temperature is raised. The theoretical significance of the failure of the Grüneisen law which is revealed by these studies will be dealt with in another communication.

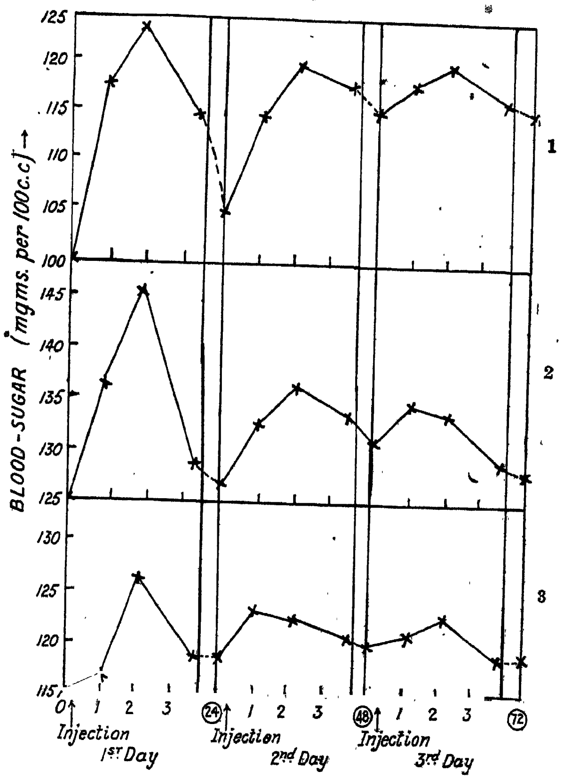
# Experimental Hyperglycæmia by Injection of Intermediary Fat Metabolism Products in Rabbits

Best and his associates[1] recently reported hydropic degeneration and degranulation of the β-cells through the injection of anterior pituitary extract similar to those observed in the remnants of Allen's partially depancreatized dogs and ascribe those to overwork. The recent findings of Dunn and his associates[2,3] on experimental alloxan diabetes have created great interest in the subject. Though this substance may bring about conditions of glycosuria and hyperglycæmia in animals, the nature of degeneration in the β-cells has been shown to be different from that caused by anterior pituitary injection or through clinical diabetes and the physiological significance has not been known as yet. Adams[4] and Joslin[5] regard obesity as a precursor of diabetes, and it is reasonable to believe that the intermediary metabolism products formed during improper oxidation of fat might be concerned in causing hyperglycæmia and other associated troubles in an individual. It may be recorded here that repeated injection of these types of chemical substances (for example, β-hydroxy-butyric acid, acetoacetic acid, pyruvic acid, etc.) have been found to cause hyperglycæmia in rabbits.

The experiment was made as follows: Adult rabbits weighing about 2 kgm. were selected and injection was given after the animals were allowed to fast for eighteen hours. Blood sugar was estimated initially before injection and after regular intervals for about 4½ hr. according to the method of Hagedorn and Jensen[6]. The animals were fed after this period with usual gram diet and again allowed to fast for



1, Aceto-acetic ester; 2, β-hydroxybutyric acid; 3, pyruvic acid.

Fig. 1.

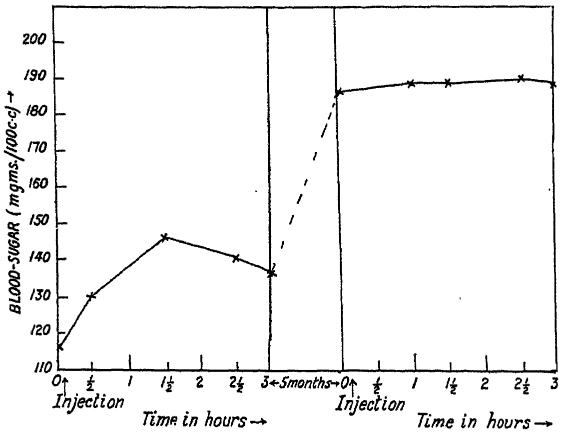


Fig. 2.

eighteen hours. The experiment was repeated for three days in succession on the same rabbits. The nature of change of blood sugar (average from two animals), during the period of experiment, is represented graphically in Fig. 1. It will be seen that in all cases the initial concentration of fasting-sugar on the third day is definitely higher than that on the first day and the nature of the curve is greatly changed. It is also interesting to record that when the set of animals receiving ethyl acetoacetate for three days was allowed to rest for about one month and the experiment repeated, the fasting blood sugar level was found to be lower than that obtained initially (that is, one month before) and a far greater hyperglycæmic effect was observed on injection of the same substance. This lowering of blood sugar level may indicate the mechanism of natural adjustment, possibly by causing hypersecretion of internal insulin. Two rabbits (male) were then injected daily, beginning with 10·0 mgm. of β-hydroxy-butyric acid and gradually increasing to 400·0 mgm. and the blood sugar curves of the animals were obtained on the very first day of injection and after the injections were continued for 150 days. The initial blood sugar value after such period of injection was found to be very high (187·0 mgm. as against 116·0 mgm. recorded on the first day) and the nature of the curve (Fig. 2) was found to be greatly changed. This curve was almost a straight one, indicating severe damage to the insulin-secreting mechanism.

It may be suggested that these intermediary fat degradation products might first stimulate the pancreatic cells, which gradually become fatigued through excessive work, possibly through lesions of these cells in the long run. Further investigations which are in progress may throw more light on the matter.

Our best thanks are due to Prof. J. K. Chowdhury and Prof. B. C. Guha for their kind interest in this work.

## Toxicity to Flies of Derivatives of Eugenol and *Cis*- and *Trans*- *Iso*eugenol

IT appears that any modification in the pentadienyl side-chain of the pyrethrin molecules induces a profound depression in the insecticidal activity[1]. Although the distribution of the double bonds in the side-chain of pyrethrolone is not yet fully established[2], there seems to be little doubt that there is either a terminal $=CHCH_3$ grouping or—less probably—the $=CH_2$ group. Allyl phenols have been found to possess insecticidal properties[3], and it appeared of interest to compare the toxicity in fly sprays of corresponding derivatives of the isomeric phenols eugenol (which contains the allyl grouping) and *iso*-eugenol (containing the propenyl grouping).

The initial tests showed that when sprayed against flies under exactly comparable conditions in kerosine or kerosine-acetone solution alone, or as adjuvants to the pyrethrins, compounds such as ethers of eugenol were usually more effective than solutions of the corresponding *iso*eugenol derivatives; but some of the results led to comparison of the *cis*- and *trans*- forms of the compounds derived from *iso*eugenol. It was then found that solutions of the *cis*- forms of the *iso*eugenol compounds approached the toxicity to houseflies shown by solutions of the corresponding eugenol compounds, whereas the *trans*- forms were noticeably less toxic in solution alone and when included with small quantities of pyrethrins.

This observation appears to be of some interest in view of the fact that comparison of the effect, as pyrethrin synergists of sesamin, of *iso*sesamin and asarinin against houseflies indicated[4] that the nature of the substituents on the benzene ring was the determining factor on the synergistic action of this class of compound, spatial configuration being of little or no importance.

The preparation and physical properties of the pure *cis*- and *trans*- *iso*eugenol derivatives employed will be described elsewhere.

## Function of Plant Vacuoles

PREVIOUSLY[1], I put forward the view that pinkish vacuoles are receptacles of enzymes for synthesis of various food reserves in plants, lower as well as higher; in support of this I produced evidence of synthesis of food reserves around the pinkish vacuoles of pyrenoids in *Spirogyra* and of synthesis of oil drops around pyrenoids in two diatoms. Additional evidence in favour of the view that pinkish vacuoles are receptacles of enzymes is now brought forward from two sources: (1) synthesis experiments; (2) plasmolysis experiments, in some fungi.

By growing fungi (*Polyporus durus* and *Phomopsis* sp.) in fatty acids and glycerine medium, the first formation of oil drops was noticed around the vacuoles in the course of two days, and by growing them in

4 per cent sucrose or glucose medium the formation of glycogen granules appeared in the same position. In a living cell intracellular enzymes never come out of the vacuoles, but remain enclosed within the vacuolar membrane; starch, glycogen, fats and proteins are synthesized just on the external surface of the vacuolar membrane, and they are also hydrolysed at the surface on account of the superficial secretion of enzymes from the vacuoles; then they are absorbed into the vacuolar cavities. But extra-cellular enzymes in fungi come out by way of exudation from the growing tips of hyphæ. Vacuoles are, thus, the seats of phenomena of synthesis as well as of hydrolysis, all reactions taking place at the surface external to the vacuolar membrane. They are not merely passive accumulators of diverse metabolic products and secreted substances soluble in water, but are the principal sites of chemical affinities in the cell due to the accumulation of enzymes.

From plasmolysis experiments in glucose, sucrose and sodium chloride solutions, it follows that when the perivacuolar membrane is damaged, there is leaking out of enzymes (proteases, diastases and lipases) which act on the protein and glycogen granules and fat drops, and transform them into soluble substances, and the mitochondria become vesiculized; their lipo-protein complex breaks down with liberation of lipides. Thus, a gradual liquefaction of the cytoplasm is brought about. The liberated lipides increase in number, some of them fuse into large globules, leading ultimately to a fatty degeneration of the hyphæ.

Experimental facts lead to the conclusion that the plant vacuoles function as storehouses of enzymes.

Details of these experiments with discussion of current theories and with illustrations are expected to be published soon elsewhere.

## Paracrinkle Virus and Inheritance

IN a recent article[1], I have argued that viruses and what I call plasmagenes[2] are derived from cell proteins. On my view, these undifferentiated proteins may come to acquire the properties either of infection or, alternatively, of inheritance, by processes of adaptation which I attempted to describe. I also represented these processes in a diagram (Fig. 3) in which arrows showed the conceivable and, to me, probable directions of evolutionary change.

Four workers in plant breeding and virus research now raise objections to this view[3]. They take the case of the paracrinkle determinant of the King Edward potato to which I referred and point out, on one hand, that it is a virus since it shows the 'carrier' as well as 'susceptible' reactions with different potato clones, and on the other hand that it is not a plasmagene.

That paracrinkle behaves as a virus was fully demonstrated by the work of Salaman and Le Pelley, to which I directed attention. In their original account they described not two but four reactions of potato varieties with paracrinkle, and a reaction of *Datura*, all fully consonant with its description as a graft-transmitted virus. I consequently referred to it as a virus and I used its behaviour as the strongest evidence, on the plant side, for my argument that viruses can arise from cell proteins and for the arrows that I drew to indicate this origin.

If, on the other hand, paracrinkle had behaved as a plasmagene I should indeed have been surprised. The possibility of so dangerous a particle being transmissible (and therefore having been transmitted) by the seed seems to me, for reasons which I gave, a remote one. I would not exclude it but I would certainly not expect it. For this reason I showed no arrows joining plasmagenes and viruses.

My critics therefore have their facts right so far as they go, but they have overlooked one enormous fact. They say, "There thus seems no fundamental difference in the reaction of King Edward to paracrinkle virus from that of any other 'carrier' variety to the virus 'carried' ". Only one fundamental difference, to be sure, namely, that King Edward *made* it, just as, I am supposing, the fowl and the mouse *made* their viruses.

It occurs to me that what my critics have not understood is the notion (which is perhaps a new one, although it seems fairly obvious) that cell proteins, characteristically produced by a nucleus of a particular new genotype, may have the capacity for indefinite self-propagation even when subject to other nuclei. Such proteins will sometimes have the potentiality of developing, either into plasmagenes or into viruses, according to their distributions in development or their opportunities in infection. They may even, by mutation and otherwise, cause cancer in the examples I have quoted.

A careful study of my article, and if necessary of the book to which it is a footnote, would, perhaps, make my premises and argument clear and leave no ground for the misunderstanding of particular phrases.

## Plant Nutrients in the Sea

IN a recent issue of *Nature*[1], Prof. J. Ritchie speculates "upon a day . . . when the International Fisheries Commission of the nations bordering the North Sea may discuss, along with its programme of researches, the allocation of sums to be contributed by each nation for chemical nutrients in the assurance that these will support a larger fish population and an increased fishing fleet in the North Sea". Prof. Ritchie surely does not realize the vast quantities involved. The English Channel is not a specially rich fishing ground, but calculations based upon the annual phosphate cycle show that the minimum value for the phytoplankton crop is about 1,400 metric tons wet weight per square kilometre each year[2]. The annual phosphate cycle involves the complete removal of this substance from the surface waters and a lesser removal in the deeper water, on account of the reduced illumination. But under each square metre the water column yields to vegetation

about 1 gm. of phosphorus, equivalent to about 7 gm. of calcium phosphate. Thus each square kilometre of sea has an annual turnover of about seven tons. To put any appreciable fraction of this quantity into the English Channel would involve a vast expenditure. Moreover, such addition would soon be dissipated into the ocean.

H. G. Wells is right in laying emphasis on the importance of phosphorus in limiting the fertility of the ocean, but his recent statement[3], that though "fisheries intercept a fraction of this phosphorus, the greater part of it forms insoluble compounds with other substances, bones, shells and so forth, and sinks slowly into the abyss beyond recovery", is incorrect. Actually the phosphate taken up is largely regenerated by excretion and decay; also the vertical circulation of the water column, which begins as the surface cools in autumn and continues until spring, brings phosphate and other nutrient salts to the well-illuminated regions again. A certain amount does sink to the abysses of the ocean. But much of this is brought up again when the oceanic currents impinge on banks and continental shelves. In this circulation, drainage from the land plays a very small part and cannot possibly account for differences observed between one year and another in such a body of water as the North Sea.

Phosphate is, of course, only one of the plant nutrients that would require to be added.

## Temporary Ponds, a Neglected Natural Resource*

NATURAL pools which contain water for a few months in spring, and are dry for the remainder of each year, are found in many parts of the world. I have examined them in Great Britain, Denmark, Sweden, Siberia[1], Canada[2], Australia and Africa. In the past little attention has been paid to ponds of this kind, except by specialists. Since they are potentially useful to man a short account of them may be of interest.

The annual history of a temporary pond in the north temperate and sub-arctic zones is as follows: With the coming of spring, and the melting of the snow which has accumulated during the winter, water collects in shallow grassy depressions and remains there for two months or more. A large number of invertebrate animals emerge from the resting condition in the soil on the bottom of the pond site, and become active within a few hours of the filling of the pool. Some animals, such as the Entomostraca, over-winter as eggs, while others, including the snails, spend the winter in the adult condition. Within one month of the formation of the pond each spring, a very great abundance of life of many kinds is found in the water, and it is in this that the usefulness of these habitats lies. When the pond dries in early summer the aquatic fauna and flora resume a resting condition, and the pond site becomes a land habitat. Because of the presence of the excrement of the water animals, the pond sites are well fertilized, and therefore support a luxuriant growth of land plants during the terrestrial phase. The leaves and stems of these land plants serve, in turn, the following spring, as food for the aquatic animals, and in that manner fertilize the aquatic phase of the pool.

In at least one respect the immediate utilization of temporary ponds is possible. In the year 1928 I was engaged in scientific work at a fish hatchery on Lake Winnipegosis, in central Canada. At this place there was need for the feeding of the fry of whitefish (*Coregonus clupeformis*) before they were planted in the lake, in order that they should have a surer start in life; in other words, in order to reduce the wastage among the fry planted in spring when there is little food in the lake waters. A suitable food supply for the fry was found in temporary ponds on shore near the hatchery. It might be assumed that once the warmer weather had come, there would be a development of fish food in the waters of the lake at an equal rate as in the temporary ponds on the shore. In practice things do not happen in that way. In the lake there is a time-lag, due in the first instance to the fact that before the biological food-producing processes can really get under way two to three feet of ice must be melted by the sun. In contrast to this, there is a very rapid development of many organisms in the temporary ponds, because those sites have been dry during the winter and so have no covering of ice; in practice it was found that the collection of plankton and organic detritus in the temporary ponds, and the feeding of it to whitefish fry, is feasible, and results in the rapid growth of the fry.

Taking a long view, it is possible to think of the efficient utilization of the plant and animal proteins and carbohydrates which are available in temporary ponds in a rationalized agriculture. Under those conditions an aquatic crop, such as plankton or fishes, could be reaped from a given piece of ground, and be followed by a field crop, such as oats. A rotation of that sort is said to be followed in carp ponds in Central Europe. Another possibility is that the site, after the drying of the pond, could be used for intensive protein-rich grazing.

In many parts of the world temporary ponds are undesirable as being a wasteful hindrance to the agriculturalist, or they may be dangerous, as breeding places of disease-carrying mosquitoes and snails. The purpose of the present note is to point out their useful possibilities. In other words, temporary ponds, so often regarded as a nuisance, are in reality a neglected natural resource.

## Surface Area of Small Objects

THE determination of the surface area of objects such as small particles or stones is of importance in many fields of research. These particles are usually convex in shape, but it seems that the mathematical theory of convex bodies is not widely known among experimental workers in this subject.

If a body is convex and has area $A$, it was proved by Cauchy that $A$ is equal to four times the mean of the area of the projection of the body on a plane for all orientations of the latter. This result has a limited application in the estimation by photographic or photometric means of the average surface area of a number of small particles suspended in a liquid. With larger particles such as stones, however, it suggests that the area of projection should be measured in a number of different directions by some such optical method. The average of these multiplied by four will give the surface area. In order to give equal weight to each observation it is desirable to choose the directions of projections to be those of the normals to a dodecahedron or an icosahedron.

The question then arises as to how good an approximation this is to the true mean. If $A$ is the true area and $A_1$ the area estimated by this method

$$0{\cdot}918 \leqslant \frac{A_1}{A} \leqslant 1{\cdot}079$$

for a dodecahedron, and

$$0{\cdot}955 \leqslant \frac{A_1}{A} \leqslant 1{\cdot}047$$

for an icosahedron. These limits are the approximate numerical values of certain trigonometrical expressions which can be evaluated exactly. They are, moreover, the best possible limits.

Proofs of the above results and some analogous theorems will appear in the *Annals of Mathematics*.

## A Solar Halo Phenomenon

A DISPLAY of mock suns was seen here on the morning of August 9. Descriptions of similar displays seen at Cambridge and Godalming have been published[1] and these notes are supplementary to them.

The Farnborough display occurred in cirrus caused by aircraft trails at a height of 20,000 ft. At 12.15 a.m. (D.S.T.) it consisted of a complete parhelic circle, about one third of a complete tangent arc, left-hand and right-hand coloured parhelia near the 22° halo, two white parhelia situated on the parhelic circle and an anthelion. The colours were exceptionally brilliant.

The shape of the tangent arc was similar to that expected theoretically[2] for the sun at an altitude of 48° 07′ (its altitude at 12.15 a.m.). The colour bands in the left-hand parhelion were not perpendicular to the parhelic circle, but were inclined to the vertical at an angle of about 30°. They also extended slightly below the parhelic circle in a manner similar to the arcs of Löwitz. Some photographs taken by Mr. Brock show this inclination. They were made on Ilford Standard Panchromatic film with a tri-red filter: the range of wave-lengths recorded was from 5800 A. to 6700 A. A measurement on the best of the photographs gives, as the distance from the inside of the 22° halo to the inside boundary of the left-hand parhelion, 8° 44′ ± 30′ (extreme error). This distance has been calculated to be 9° 31′, assuming a refractive index of 1·307 for ice (corresponding to a temperature of − 10° C. and a wave-length of 6700 A.) and a solar altitude of 48° 07′. As it has been assumed that the sun is a point source, the agreement seems satisfactory.

The bands seen by Mr. Archenhold were also seen here; but according to our notes they were coloured, even when they passed through the sun. This indicates a diffraction origin for the colours. Unfortunately, it was not noticed whether the red or violet was nearer the sun; such an observation would have distinguished a refraction origin from a diffraction origin. We think that Mr. Archenhold's explanation is too simple, since it is geometrically impossible for a collection of reflecting and refracting elements between earth and sun to produce a straight band of light not passing through the sun, except for unlikely distributions of orientation.

It is evident that knowledge of atmospheric optics is still in an elementary state, and that many more careful (preferably photographic) observations are required. That England is not an unsuitable country for these observations is shown by the fact that, during the five weeks following the display, we have seen fifteen 22° solar halos, three brightly coloured parhelia, one isolated upper tangent arc (probably often mistaken for part of a 22° halo) and one 17° solar halo.

## Prof. A. E. Conrady

I AM indebted to Mr. Cyril Young, of Sir Howard Grubb, Parsons and Co., Ltd., for directing my attention to a mis-statement in my obituary notice of the late Prof. Conrady[1]. I had been informed from a source which I believed trustworthy that, prior to the War of 1914–18, the periscopes fitted to British submarines had been obtained from foreign sources. Mr. Young, supported by other correspondents, assures me that almost all the periscopes of this period were made by the firm of Sir Howard Grubb and Sons, Ltd., in Dublin; and this firm produced the majority of the periscopes used during the War. Even before 1914, periscopes were the main product of the firm, though it was probably better known in scientific circles for its astronomical telescopes. Sir Howard Grubb took out a number of patents in connexion with submarine periscopes from the year 1901 onwards. The firm's workshops were removed from Dublin to St. Albans when the enemy submarine menace became acute.

This does not, of course, detract from the merit of Prof. Conrady's original work in the design of such complicated systems (his designs were not of the 'Grubb' type) and his efforts, together with those of the optical staff of the National Physical Laboratory, Messrs. W. Watson and Sons, Ltd., and Messrs. Kelvin, Bottomley and Baird, Ltd., must have contributed very largely to the adequate supply of these essential parts of submarine equipment. Their manufacture was later taken up by Messrs. Barr and Stroud, Ltd.

It is clear that Great Britain owes a great debt to the late Sir Howard Grubb in this connexion.

# THE BEECH TREE

By ALEXANDER L. HOWARD

Hinc olim juvenis mundi melioribus annis,
Fortunatarum domuum non magna supellex
Tota petebatur ; sellas, armaria, lectos,
Et mensas dabat, et lances, et pocula Fagus.

Hence, in the world's best years, the humble shed
Was happily and fully furnished :
Beech made their chests, their beds, and the join'd-stools :
Beech made the board, the platters, and the bowls.
COULEIUS.

JULIUS CAESAR, after visiting Britain, returned home and reported that he had seen vast forests containing oak, ash, elm, and other trees in great abundance, and as he mentioned the trees by name, omitting the beech, it was thought that this tree was not indigenous to the country. C. A. Johns suggests that like some other explorers Julius Caesar was given to exaggerate the importance and extent of his travels, and conveyed the impression that he had penetrated farther into the country than was actually the case. Since he only traversed part of Sussex and Kent, and was in England only a few days, his report was of little account. Elwes, in "Timbers of Great Britain and Ireland", dismisses the subject once and for all by his pronouncement as follows :

"The beech is indigenous to England. Remains of it have been found in neolithic deposits at Southampton Docks ; Crossness, in Essex ; in Fenland ; in pre-glacial deposits in the Cromer forest bed ; and at Happisburgh, Norfolk. Names of places of Saxon origin, in which the word beech occurs, are very common, as Buckingham, Buxton, Boxstead, etc. . . . The beech is not believed to be indigenous in Scotland and Ireland, and no evidence is forthcoming of its occurrence in prehistoric deposits in those countries."

Johns, telling a story which he considers may be a fabrication, says :

"Among the many anecdotes connected with the history of printing which have come down to us, that related by Hadrian Junius deserves to be noticed in this place. About the year 1441, Lawrence Koster, a citizen of Haarlem, 'walking in a suburban grove, began first to fashion Beech-bark into letters, which being impressed upon paper, reversed in the manner of a seal, produced one verse, then another, as his fancy pleased, to be for copies to the children of his son-in-law'. This hint he subsequently improved upon, and finally invented blocks of lead and tin, and printed books. Among his workmen was John Faust, who, having been initiated in the art, although sworn to secrecy, decamped, carrying with him his master's stock in trade, and set up as a printer on his own account at Mayence. I should add that, although many literary men have credited this account, it bears, on close examination, internal evidence of being a fabrication, either of Hadrian or his informant."

The beech tree (*Fagus sylvatica*) with a smooth green trunk and a massive crown, covered in the early spring with vivid light green leaves, which darken as the year advances, changing in the autumn to a golden tint, is one of the most beautiful of all our forest trees.

The shade which it provides has been gratefully accepted by all people for two thousand years, and probably longer.

Pliny says :

"There is a little hill named carne within the territorie of Tusculum, not far from Roman Citie side, clad and beautiful with a goodly grove and tuft of Beech trees, so even and round in the head, as if they were curiously kept cut and shorne artificially with garden sheares : . . . In it there was one especiall faire tree above the rest, which Pabienus Crispus ; a man in our daies of great authoritie . . . cast a fancie and extra ordinarie liking unto : insomuch as he was wont not onely to take his repose and lie under it, to sprinkle and cast wine plentifully upon it, but also to clip, embrace and kisse it other whiles."

Strutt says :

"The Beech will grow in the most stoney and barren soil. In sheltering exposed situations it is particularly desirable on account of its retaining its leaves until the very end of Autumn, and indeed many of them throughout the winter. Their delicate green gradually fading to a modest brown, then to golden orange and at last to the more appropriate red."

In France it has been no less highly esteemed. Elwes says :

"in the North of France it attains perfection and forms very large forests . . . the finest beech forest in France is that of Retz which contains 37,000 acres . . . the beeches contain 329,433 c. ft. of timber, and reach a height of nearly 150 ft. with clean stems of 80 to 90 feet. Their age in 1895 was 183 years, and they were considered (then) to have reached their maximum development."

Later he mentions one of the finest beeches in France called "La Bourdigalle" in the Forêt de Lyons, which is supposed to be 375–575 years old. It is generally considered that in England the beech tree lives for about 250–400 years, probably reaching its prime in less than 200 years, after which time it gradually declines, invariably, as in the case of many trees, becoming hollow.

Strutt mentions the King Beech, in Knole Park, which in 1830 was "105 ft. high, 24 ft. in girth at 13 ft.", and it is interesting that Elwes mentions the same tree as follows : "in 1905 100 ft. by 30 ft. in girth at 5 ft. It has the largest girth of any beech I know of now standing in England". Mr. Mason, kindly instructed by Lord Sackville, has sent me the following note under date of May 18, 1944, regarding this tree :

"The Beech is now very much the worse for wear, only one of the main arms now being left. I have measured this at 13 ft. and it measures 37½ ins. quarter girth (150 in. circumference), I have also measured the main bole at 5 ft. ; this now measures 32 ft. in circumference. The height of the remaining portion of the tree is about 90 ft. It is now in full leaf."

It is interesting to notice that Pliny, 1,500 years ago, records the practice of the Greeks and the Romans who found themselves unable to resist the temptation of carving their names on the beech trees, and that the same habit is continued up to the present day.

While the beech, with its dense overhead crown, affords a welcome shade and a cooler temperature on hot summer days for the traveller, it is a greedy occupant of the surrounding ground. Unlike the plane, and the alder, its dense shade prevents flowers or grass from growing under it. The only compensation is one of which advantage is taken by the more thrifty people in Europe, extending from France to the confines of Italy and Greece. This consists of the truffles and morels which thrive beneath the beech tree. In Germany and France these fungi are eagerly collected and form an important food. Truffles were originally valued in England, and dogs were especially trained for finding the fungus, which grows somewhere under the surface of the ground ; a practice which, of late years, seems to have almost completely disappeared. On

the Continent, especially France, pigs are still used for this purpose.

Johns, speaking of the truffle, says:

"It possesses a strong but agreeable smell, and is generally found by dogs and pigs trained to search for it: but, in those countries where truffles abound, in October (which is their season for ripening) all the inhabitants repair to the woods, slightly stirring, or rather scratching the ground in those places which experience points out to them as the most likely to contain the tubers. The high price of, and constant demand for truffles, both in France and other countries, renders this a very lucrative employment, and experienced hunters are rarely deceived in the places where they make their search."

Berkeley quotes an instance of a poor crippled boy who could detect truffles with a certainty superior even to that of the best dogs, and so earned a livelihood. And as regards morels:

"In England they are comparatively rare, but Mr. Berkeley states that he has known them to be so abundant in Kent, as to be used for making a sort of catsup."

Forty-four years ago, in Norfolk, Sir Hugh Beevor took me with him on a search for truffles, which proved successful.

The great importance of the beech tree is not limited to its beauty and shade or even to its immense value for timber, but in addition it is recognized as one of the most important of those trees which help and foster the growth of all other forest trees. Step, who refers to the beech by the title of "Mother of Forests", very mistakenly says that "the timber has little importance", but he is quite correct in acknowledging "his heavy indebtedness to this Nursing Mother". Curiously, however, in later life, it is aggressive and overbearing, so that any woodland of mixed trees, even including oak, will be dominated and eventually expelled by the beech.

Of late years demand for this timber has exceeded all bounds, and among the forests and woodlands of England no tree has been more ruthlessly cut down.

Only a few years ago the country around High Wycombe seemed to provide an inexhaustible supply of beech trees suitable for chair and furniture manufacture. The industry is so old that it is difficult to discover when it first started, but until quite lately the early primitive pole lathe could be seen turning the chair legs in the beech woods, exactly as it was used hundreds of years ago. The pole lathe, together with the other tools employed in the work, was well illustrated in the issue of the *Woodworker* of May 1939. This consists of an upright or similar stake, to which a pole is attached at right angles. Thonging is attached to the pole and this is taken to the lathe. "The thonging passes round the work and causes it to revolve as the treadle moves downwards. The spring of the pole causes the treadle to be drawn up again ready for another stroke. The cut is made on the down stroke only." The supply of beech trees at High Wycombe which seemed at one time to be inexhaustible has vanished, and for some years past those engaged in the trade have had to go farther and farther afield for their timber, and even to import immense quantities from southern Europe.

Among many large sales, especially during the War of 1914–18 and up to the present, in every district where beech trees were available, one transaction stands out noticeably. This concerned one single sale of beech trees at Goodwood, when no less a sum than £55,000 was paid by the purchaser. I have been informed that most of this timber was sold in High Wycombe. I have also been informed that the destruction of these glorious woodlands was necessitated by the incidence of taxation to meet death duties. While this may be perhaps the largest single case on record, it is in no manner the only case, as the same thing has been happening in every part of Great Britain for a great many years past. Successive Governments, while wholly neglecting to make any provision for the reafforestation of the country, have at the same time brought about the deforestation year by year, so that to-day the situation has become dangerous to the welfare of the community.

Every account during 1,500 years has emphasized the usefulness and good qualities of the timber of beech, and for the last hundred years it has perhaps been only second or third in importance in our woodworking industries.

The wood is of a light brown colour, tough but soft, with a straight grain, easily worked, and presenting a smooth surface from both machine and hand tool, whether on the transverse, longitudinal, or across the grain. The extensive fine medullary rays, radiating from the centre to the outside, show when cut in multitudinous flecks. The shrinkage in seasoning is moderate, and with good air or kiln-drying presents even surfaces. Although beech when properly ventilated is fairly durable, if unventilated it rapidly decays, but under water, or ground where there is moisture, it is very durable. About thirty-five years ago, when the underpinning of Winchester Cathedral was necessary, round beech trees and oak were removed which were perfectly sound. The trees had been secured with pegs, some of beech wood, which were sound after more than five hundred years in position. Round piles of beech were taken up from the foundations of Waterloo Bridge, sound after sixty to seventy years of immersion in the bed of the Thames.

Beech has been a favourite wood with chair-makers for two hundred years and perhaps more. The higher-class makers working with walnut, oak, or mahogany, satinwood, etc., generally used beech for the frames; but it is noticeable that Chippendale never employed it. Many fine specimens of artistic design and clever craftsmanship have been lost as the beech framework used was attacked by the *Lyctus* or *Zestobium* beetles, or both, the framework rapidly turning to dust, and the chairs breaking up. The Master's chair, presented to the Glass Sellers Company in 1702, is a superb specimen constructed of walnut and beech; it is still in perfect preservation; but the beech framework had to be replaced this year to prevent collapse. Three other Jacobean chairs of exquisite English marquetry were similarly affected.

Immense quantities of the wood have been used for making a cheaper class of chair for halls, kitchens, and the well-known wheel-back chairs. This trade has been carried on extensively at High Wycombe and elsewhere. Innumerable articles have been made of beech, such as brush-backs, bowls, bread trenchers, and all kinds of domestic utensils. Many of these and also bedposts have been carved with the wheat-ear and other designs. Indeed, throughout the ages civilized man has recognized the merits and usefulness of this wood, for Pliny tells us:

"As touching the beech, the grain of it runneth rosse two contrarie waies like combe teeth; but in old time the vessels made of that wood, were highly esteemed. As for example Marius Curius having subdued his enemies, protested and bound it with an oath, That of all the bootie and pillage taken from them, he hath not reserved anything for himselfe, but only a cruet or little ewer of Beeche wood, wherewith he might sacrifice unto the gods."

Since the present War, the beech tree has come into prominence for the manufacture of ply-wood, with such success that the demand is likely to increase beyond expectation. The Ministry of Supply has now given instructions that all beech being felled in the British Isles shall first be inspected and suitable butts reserved for this purpose.

The very beautiful and ornamental tree generally known as the copper beech is a variety of the purple beech (*Fagus sylvatica* var. *purpurea*). The origin of this tree is doubtful. Elwes says:

"Mention is made of a beech wood at Buch, on the Irchel mountain in Zurichgau (commonly called the Stammberg) which contains three beech trees with red leaves, which are nowhere else to be found . . . and the legend is stated that according to popular belief five brothers murdered one another on the spot where the trees sprang up. Offspring of these trees were carried into a garden, where they still retained their purple colour."

As to the romantic origin above-mentioned, there may possibly be a difference of opinion. This tree can be found widely distributed and is highly prized in innumerable places throughout Great Britain and on the Continent. Its highly decorative appearance in parks and gardens should ensure its future success and planting. Within the last twenty-five years, on two separate occasions I have heard of the successful transplantation of two splendid fully-grown trees—a significant illustration of its appreciation by the respective owners. Elwes mentions that the largest tree which he had found was in the park at Dunkeld, Perthshire, which measured 86 ft. high, with a girth of 15 ft. 3 in.

Nor must we overlook among numerous varieties of this beautiful tree the fern-leaved beech, sometimes called the 'cut-leaved' beech, for which a number of different botanical names have been used, but which Elwes names var. ***heterophylla***: the origin of this variety is unknown. This tree is far too little known; but its ornamental character and the decorative beauty of its foliage should recommend it for more general cultivation.

## CHEMICAL RESEARCH IN THE U.S.S.R.

RECENT Russian publications received contain many papers of considerable interest dealing with chemical and physico-chemical subjects. Only a small number of them can be mentioned here.

Although polonium belongs to Group VI in the Periodic System, no compounds in which it shows a valency of six were known, although compounds of lower valencies have been described. A. G. Samartzewa[1] examined the co-precipitation of polonium with salts of telluric acid, containing 6-valent tellurium, and found that polonium crystallizes isomorphously with salts of orthotelluric acid. This suggests that polonium forms an ion $PoO_4''$ in which it is hexavalent.

The Debye formula for the dipole moment of a molecule in terms of the dielectric constant is restricted to gases and to very dilute solutions of polar substances in non-polar solvents. In the case of pure polar liquids the effective orientation polarization is less than the ideal orientation polarization,

$$P_i = \frac{4}{9}\pi N \frac{\mu^2}{kT},$$

which, if known, would give the dipole moment $\mu$. The difference is probably due to the internal local field in the liquid. J. K. Syrkin[2] has found two formulæ which give the relation between effective and ideal polarizations, from which the dipole moment $\mu$ for a pure liquid can be determined if its refractive index $n$, density $d$, and dielectric constant $\varepsilon$ are known ($N$ is Avogadro's number, $k$ is Boltzmann's constant, $M$ is molecular weight, $T$ is absolute temperature):

$$\frac{4}{3}\pi N \frac{\mu^2}{3kT} = \frac{(\varepsilon-n^2)(\varepsilon+2)}{(n^2+2)(2\varepsilon-1)}.$$

A formula for mixtures is also given, and can be used when the substance is soluble only in a polar solvent.

The relation between colour and structure of organic compounds has often been dealt with both theoretically and experimentally. A theory based on quantum-mechanical resonance was proposed by Sklar[3]. An increase in the number of conjugated bonds is accompanied by an increase in the number of resonance structures, which probably tells upon the absorption spectrum and colour. M. A. Kovner[4] has considered quantitatively the energy-levels and spectrum of hexatriene, and gets good agreement with the known absorption band.

Among the many suggestions for the structure of boron hydrides, one by M. E. Dyatkina and J. K. Syrkin[5] supposes that there are no single electron bonds but resonance between the states $>B^+$ and $>\overline{B}<$, and the structure of $B_2H_6$ is represented as follows. Two atoms of boron and four of hydrogen are in one plane and the remaining two hydrogens are on a line perpendicular to this plane and passing through the middle of the line B—B at equal distances from the plane. This model represents two distorted tetrahedra having a mutual edge. The model is discussed in the light of the electron diffraction measurements of Bauer and, in the opinion of the authors, is consistent with them. Structures for metal borohydrides are also proposed.

The mechanism of discharge of hydrogen ions has, as is well known, attracted a considerable amount of attention in recent years, and different theories have been proposed. A paper by A. Frumkin[6] gives a survey of his experiments. The lack of agreement of data on the over-voltage on mercury is traced to the deposition of impurities, especially near the electro-capillary maximum. The results with high current densities obtained by other workers are critically considered and shown to be really in agreement with Tafel's equation. Measurements with very low current densities are very difficult, on account of the possibility of depolarization by dissolved oxidants, and the danger of adsorption of surface-active substances. For very low current densities the time lag in charging the double layer also comes in. There is some disagreement with Bowden and Kenyon's results, but not much. The results with dropping electrodes are considered in detail. The shift of half-wave potential with concentration found by Tomeš was not confirmed. A very detailed discussion of the structure of the double layer is given, and, among other conclusions reached, it is shown that results cannot be explained on the assumption that the potential depends only on the distance from the mercury surface.

# WORK OF THE LA PLATA ASTRONOMICAL OBSERVATORY

BERNHARD H. DAWSON has a paper with the title, "Observaciones De Planetas y Cometas", published at the La Plata Astronomical Observatory, which deals with his observations during the years 1940–41 (*Obs. Ast. Univ. Nac. de la Plata*, **6**, No. 7). The work was carried out with the equatorial instruments of the Observatory, and the visual observations were effected with the filar micrometer of the refractor with aperture 433 mm., using a dark field illuminated with red light. A brief description of certain methods and precautions to ensure accuracy is given. On several occasions it was found necessary to use relatively faint stars as reference points owing to the limited field, but no difficulty was experienced in this procedure, thanks to the "Astrographic Catalogue".

Photographic observations during the first years of earlier observations at the Observatory were carried out entirely by means of the "Astrographic" objective, aperture 342 mm. and focal length 3,417 mm., but more recently the "UV" objective, aperture 160 mm. and focal length 1,500 mm., has come into general use. It was found that the smaller aperture was largely compensated by the greater clarity of the images, and in addition to certain advantages, its larger field is of assistance in the search for planets of uncertain position, and in other ways as well.

In the photometric work on Eros, compensation of half the apparent motion of the planet was effected during the exposures, so that the images of the planet should present the same aspect as those of the stars, and thus could be compared photometrically. Unfortunately, the atmospheric conditions were not favourable for this work, clouds intervening on many occasions. A table shows the positions of Eros during May 28–September 26, 1940, and another table supplies details of the photometric observations during June 11–August 23 in the same year.

Positions of Comets Cunningham, 1940 *b*, Whipple, 1940 *d*, van Gent, 1941 *d*, and Schwassmann-Wachmann, 1941 *f*, are also supplied for a number of dates.

Gualberto M. Iannini has published three papers with the titles, "Medidas Micrometricas De Estrellas Dobles"; "Posible Movimiento Rectilineo De β 311"; and "Una Nueva Determinacion De La Orbita De Ψ Argus" (*Obs. Ast. Univ. Nac. de la Plata*, **6**, No. 8). The first of these papers describes the author's measurements of double stars. The micrometer was used in connexion with the equatorial refractor, aperture 433 mm., and the measurements were generally made when the hour angle was less than two hours. Six readings of the position angle were taken, three with the eyes parallel to, and three with the eyes perpendicular to, the micrometer wires, thirty-six stars in all being dealt with. Details of the results are set out for each star in columns which supply the year and fraction of a year of the observation (1900 being taken as the basis), position angle observed, mean distance, etc.

The second paper deals with the possibility of rectilinear motion of the system β 311, the components of which are of magnitude 6·7 and 7·0. The equations expressing the movement of the system in right ascension and declination show that there is an annual relative movement of 0·0182″ in a direction 130·25° and a minimum distance of 0·336″, with an angle of 40·25° for the year 1941·5. A table gives the relation between observation and calculation, from 1875·92 to 1937·08, and with two exceptions, it shows that the hypothesis of rectilinear motion is satisfactory. A definitive solution of the problem, however, cannot be effected at present.

In the third paper the elements of the orbit of Ψ Argus are re-determined from forty-one observations. The companion having made considerably more than a revolution since its discovery in 1883·3, the two dynamical elements can be determined by means of a graphic method, and the other elements were obtained by the method of Zwiers. Residuals revealed the presence of a systematic error, and corrections were applied which gave a new orbit. It is interesting to know that Van de Bos had also revised the orbit and his results, not yet published, were brought to the notice of Iannini after the completion of his work. With the exception of *a*, the two sets of elements differ by amounts which do not exceed 2½ times Iannini's mean errors.

# MAN: THE FIRE-USING ANIMAL

ON March 8 last the Association of Czechoslovak Scientists and Technologists was addressed by Dr. G. W. Himus on "Man: The Fire-Using Animal". Although the lecture started with an account of the origin and the rise of the use of fire by mankind—or as suggested 'fuel squandering'—in the main it surveyed the present state of fuel supplies and prospective fuel technology in Great Britain. Noteworthy is the slowness with which Great Britain became conscious of the importance of efficiency in getting and consuming coal—doubtless owing to the abundance, high quality and cheapness of British coal together with the slender scientific outlook. Without this, waste cannot be recognized, still less corrected. Moreover, in some industries, the cost of fuel is a relatively small item of the cost of production and consequently failed to arouse the attention of the management.

Nevertheless, a time arrived when the importance of a more rational use of coal came to be recognized. It was even found worthy of a place in university studies—at Leeds in 1906, at the Imperial College in 1912, while the Fuel Research Board was established during the War of 1914–18. The two Wars which followed shook the complacency of the State and industry, by the scarcity and steep rise in prices, and in the present War, by the development of acute scarcity.

Although, during the past, knowledge of efficiency in the use of fuel has advanced, experience in the national campaign for fuel saving has revealed a lag in the application of this knowledge. The author illustrates the advance in fuel efficiency by the performances of large industries accustomed to employ considerable technical assistance. These include the public utilities, iron and steel industries and the coal mines. The net saving of coal of these in the period between the two Great Wars is estimated by the author to reach thirty-two millions of tons of coal per annum, while the total saving may be considerably higher. This is a very large quantity of fuel, to supply which would have been a great embarrassment to the Ministry of Fuel and Power to-day.

Some matters of importance, both topical and future, are examined. Emphasis is given to the need

for greater application of technical training for the smaller industrial units—possibly by co-operative effort. The sale of solid fuel in small quantities by weight without allowance for calorific value is criticized. It must, however, be recognized that there are peculiar difficulties, and in some countries solid fuel is sold by volume. The heating value of gaseous fuels in public supply can be easily controlled, whereas it cannot vary appreciably in the case of liquid fuels of given chemical character. Moreover, coal as mined contains variable proportions of incombustible matter, sometimes hard to separate. It is often overlooked that the cleaning of coal involves the production of considerable quantities of coal 'fines' or 'slurry' of little or no commercial value, while accumulations of small coal, if ignited, may become a public nuisance. For steam raising, it is considered possible that consumers will have to adapt themselves to the use of a lower grade of coal. Already the need for widening the range of fuel in use has caused official encouragement to be given to the installation of suitable mechanical equipment.

The lecture mentions a number of fuel problems still in the more speculative stage, and in all gives an interesting survey of the questions now in the minds of modern fuel technologists. H. J. Hodsman.

# FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Saturday, October 14

Association for Scientific Photography (at Caxton Hall, Westminster, London, S.W.1), at 2.30 p.m.—Mr. H. Emmett: "Cinemicrography of Crystal Growth"; Mr. R. McV. Weston: "Cinemicrography in Biological Research".

### Monday, October 16

Institution of Electrical Engineers (London Students' Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—"Brains Trust" Meeting.

Association of Austrian Engineers, Chemists and Scientific Workers in Great Britain (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 7.30 p.m.—Mr. E. Pribram: "Jet Propulsion, Rocket Propulsion".

### Tuesday, October 17

Institution of British Agricultural Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2 p.m.—Mr. Cornelius Davies: "Harvesting Machinery".

Society of Chemical Industry (Agriculture Group) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. H. C. Gough: "Soil Insecticides".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. Innes H. Pearse: "The Health Centre and the Family".

Chemical Society, the Royal Institute of Chemistry, and the Society of Chemical Industry (Edinburgh Sections) (joint meeting with the Edinburgh University Chemical Society) (in the Medical Chemistry Lecture Theatre, The University, Teviot Place, Edinburgh), at 7 p.m.—Prof. G. F. Marrian, F.R.S.: "Some Aspects of Heroid Metabolism".

### Wednesday, October 18

Institute of Fuel (North-Western Section) (at the Engineers' Club, Albert Square, Manchester), at 2.30 p.m.—Mr. G. N. Critchley: "The Economics of Saving Fuel, with particular reference to the Insulation of Steam Ranges".

Institution of Electrical Engineers (Transmission Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. W. Grimmitt: Inaugural Address as Chairman.

British Association of Chemists (London Section) (at Wigmore Hall, Wigmore Street, London, W.1), at 6.30 p.m.—Discussion on "The Safeguarding of Key Industries" (to be opened by Mr. Norman Sheldon).*

Iron and Steel Institute (joint meeting with the Manchester Metallurgical Society and the Institute of Metals) (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Prof. H. W. Swift: "Deformation of Metals".

### Thursday, October 19

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Prof. Wilson Baker: "Non-benzenoid Aromatic Hydrocarbons" (Tilden Lecture).

Institute of Fuel (East Midlands Section) (in the Lecture Theatre of the Nottingham Corporation Gas Department, Parliament Street, Nottingham), at 3 p.m.—Dr. E. W. Smith and Mr. Theodore Turner, K.C., will speak at a Conversazione.

Society of Chemical Industry (Road and Building Materials Group) (at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 5 p.m.—Mr. D. C. Broome: "The Substitution of Coal Tar Pitch for Asphaltic Bitumen in Building Mastic".

Society of Chemical Industry (Newcastle Section) (at the King Edward VII School of Art, King's College, Newcastle-upon-Tyne), at 5.45 p.m.—Mr. J. Brown: "Assay of Coal for Carbonisation Purposes".

### Friday, October 20

Institution of Electrical Engineers (Measurements Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. W. G. Radley: Inaugural Address as Chairman.

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. H. R. Ricardo, F.R.S.: "Applied Research" (Presidential Address).

North-East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6 p.m.—Annual General Meeting. Sir Summers Hunter: Presidential Address.

### Saturday, October 21

British Rheologists' Club (at the University, Reading), at 2.30 p.m.—Annual General Meeting. Discussion on "The Measurement of Tack" (Introductory Papers by Dr. N. A. de Bruyne and Dr. R. F. Bowles).

Sheffield Metallurgical Association (at 198 West Street, Sheffield, 1), at 2.30 p.m.—Mr. A. Preece: "The Oxidation of Steels in Furnace Atmospheres".

Quekett Microscopical Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. Nellie B. Eales: "Some Aspects of the Malaria Problem".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (full-time) in Chemistry, and a Lecturer (full-time) in Engineering for Day and Evening Classes—The Principal, College of Technology and Commerce, The Newarke, Leicester (October 18).

Mathematics Master for the Junior Day Technical School for Boys—The Principal, Wimbledon Technical College, Gladstone Road, London, S.W.19 (October 20).

Mathematics Master in the Bristol Junior Technical School—The Chief Education Officer, 2 Cecil Road, Clifton, Bristol, 8 (October 21).

Lecturer (full-time) in Engineering Subjects in the Medway Technical College, Gillingham—The District Education Officer, Fort Pitt House, Rochester (October 21).

Assistants at the Fuel Research Station, Blackwall Lane, Greenwich, London, S.E.10, for abstracting and translating scientific literature relating to Fuels (candidates should have qualifications in one or more of the following subjects: Chemistry, Physics, Engineering; together with a good knowledge of French and German)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2985.A) (October 21).

Experienced Organic Microanalyst—The Professor of Organic Chemistry, Imperial College, South Kensington, London, S.W.7 (October 21).

Electrical Engineer to the Borough of Darwen—The Town Clerk, Town Clerk's Office, Darwen (endorsed 'Electrical Engineer') (October 23).

Works Engineer for development of a permanent Electro-chemical Plant in South Wales—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2303.XA) (October 23).

Borough Electrical Engineer and Manager to the Borough of Willesden—The Town Clerk, Town Hall, Dyne Road, Kilburn, London, N.W.6 (endorsed 'Borough Electrical Engineer and Manager') (October 23).

Principal of the Blackburn Municipal Technical College, and Head of the Textile Department—The Director of Education, Education Office, Library Street, Blackburn (October 23).

Lecturer in Mathematics, a Lecturer in Physical and Inorganic Chemistry, and a Lecturer in Mechanical Engineering—The Principal, Brighton Technical College, Brighton (October 23).

Food Chemist in Food Standards and Labelling Division, Colwyn Bay—The Ministry of Labour and National Service, Central Register, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.3042.A.) (October 24).

Borough Engineer and Surveyor—The Town Clerk, Town Hall, Kensington, London, W.8 (November 1).

Speech Therapist—The Chief Education Officer, West House, Halifax.

Teacher mainly for Mathematics and Engineering Science in the Junior Technical School and in Senior Day and Evening Classes—The Principal, County Technical College, Gainsborough.

Graduate Assistant Master to teach Mathematics, Science and Engineering Drawing in the Junior Technical School and National Certificate Classes—The Director of Education, 8 Warrington Street, Ashton-under-Lyne, Lancs.

Lecturer in Geography—The Principal, Training College, Lincoln.

Assistant Curator for the Kaffrarian (Natural History) Museum—The Director, Kaffrarian Museum, King William's Town, C.P., South Africa.

# THE UNITED NATIONS: A PROPOSAL FOR INTERNATIONAL SECURITY

FOR more than five years of war, the conditions of peace and the means and organization to ensure peace have been discussed with a thoroughness and earnestness accentuated if anything by the vicissitudes and ordeal through which the United Nations have passed. The causes of the failure of the League of Nations have been probed and analysed dispassionately, and the reasons for the comparative success of other international agencies such as the International Labour Organisation have been scrutinized with the view of throwing the fullest light on the principles to be served in any subsequent attempt to build a new world organization. Even at the end of 1939, serious studies were being initiated by Political and Economic Planning and by the Royal Institute of International Affairs into the various aspects of international co-operation. The quality of the resultant studies and much of the voluminous literature of the ensuing years, with such outstanding books as Prof. E. H. Carr's "Conditions of Peace", Lord Cecil's "A Great Experiment", Mr. Harold Butler's "The Lost Peace" and Mr. R. M. Reyner's "The Twenty Years' Truce", has reached a level that provides solid ground for believing that a much more scientific approach to the whole question of world organization has become possible.

Moreover, it is realized that there are lessons to be drawn from the Armistice of 1918, and the consequences which flowed from the premature termination of the organizations set up to forward the Allied war effort, such as the Inter-Allied Shipping Control. That realization is reflected in an obvious desire to see that such agencies as the Combined Raw Materials Board, the Middle East Supply Centre and the like, shall be used to serve the purposes at least of the interim period of re-settlement and reconstruction.

That much can be discerned as a matter of general agreement, whether or not we accept in full the arguments of the functional school of thought, as represented by Prof. Mitrany, who see in the development of functional services to meet specific ends and needs the most hopeful way to build up a world organization in which resort to war is obsolete. Others, such as the American spokesmen Mr. Walter Lippmann and Mr. Sumner Welles, impressed by the Atlantic Community or by Pan-America, find the solution in regionalism; while others again, such as Sir John Fisher Williams, insist on the importance of dealing with the causes of international differences by peaceable discussion before they become critical, and on limiting action to what is possible at the present stage of human development. Another school of thought urges federation as the solution, either on the lines outlined by Clarence Streit in "Union Now" or in a more limited form by Mr. Lionel Curtis. Others again, recognizing that an international organization which is to achieve its purposes must have strength to give effect to its decisions, have

concerned themselves with the ways and means of putting teeth into the Covenant.

In contrast to the discussions on world organization earlier in the War, there has been a significant tendency of late to reconsider the verdict on the League of Nations, and to attribute its failure not to the machinery but to the lack of drive and sincerity behind it. Writing to Lord Cecil on his eightieth birthday recently, the Prime Minister said: "This war could easily have been prevented if the League of Nations had been used with courage and loyalty by the Associated Nations", and went on to speak of acting "in accordance with the spirit and principles of the League, but clothing those principles with the necessary authority". Any workable system must be a compound of realism and idealism, and in a problem of such complexity all simple formulæ are rightly suspect.

The tentative proposals for the establishment of a general international organization under the title of "The United Nations" which have now been published as an outline agreement reached between the delegations of Great Britain, the United States, the U.S.S.R. and China at Dumbarton Oaks, Washington, during August 21–October 7 on the maintenance of peace and security after the War fairly reflects this tendency. Superficially at least, they bear a marked resemblance to the old League of Nations. Membership of the organization is open to all peace-loving States, and the organization, like the League of Nations, will possess four principal organs: a General Assembly, a Security Council, an International Court of Justice and a secretariat, with such subsidiary agencies as may be found necessary. All members of the organization will be members of the General Assembly. While the General Assembly may initiate studies and make recommendations for promoting international co-operation in political, economic and social fields or for co-ordinating the policies of agencies in such fields, it will not consider concurrently any matter relating to the maintenance of international peace and security which is being dealt with by the Security Council. Again, while it may consider the general principles of co-operation in this field, questions in which action is necessary will be referred by the Assembly to the Security Council before or after discussion. These are important differences from the League's constitution.

The Security Council is to consist of eleven members, five permanent and six elected by the General Assembly for a term of two years, three retiring and not being eligible for immediate re-election. The permanent members designated are the United States, the United Kingdom, the Union of Soviet Socialist Republics, China, and, in due course, France. This Security Council will be charged with the primary responsibility for the maintenance of international peace and security.

Some of the draft proposals recall in substance the articles of the Covenant, but there are notable omissions and additions. The Security Council is empowered to investigate any dispute or situation which may lead to international friction or give rise to a dispute, in order to determine whether its continuance is likely to endanger the maintenance of international peace or security, and any State, whether a member or not, may bring any such dispute or situation to the attention of the General Assembly or of the Security Council. But while Article 2 of the Covenant is thus shadowed, there is nothing that corresponds with Articles 13 and 15. The Security Council may call upon the parties to such a dispute to settle their differences in accordance with their obligation under the Charter by negotiation, mediation, conciliation, arbitration, judicial settlement or other peaceful means, as contemplated by Article 12, but neither the Security Council nor the General Assembly is charged with the duty either of conciliation or of investigation and report.

It is in the section which replaces the sanctions clauses of the Covenant that the major departures from the old League of Nations appear. The Security Council, having determined the existence of a threat to the peace, is empowered to determine what diplomatic, economic or other measures not involving the use of armed force are required to maintain or restore peace and security, and to call upon members of the organization to apply such measures. If the Security Council considers such measures inadequate, it is also empowered to take such action by air, naval or land forces as may be necessary. To that end, all members of the organization, not merely the members of the Council, are to accept the obligation not only to apply the diplomatic, economic and like sanctions but also "to make available to the Security Council, on its call and in accordance with a special agreement or agreements, concluded among themselves, armed forces, facilities, and assistance necessary. . . ." In particular, for urgent military measures, there are to be "held immediately available by the members of the organisation national air force contingents for combined international enforcement action".

Plans for the application of armed force are to be made by the Security Council with the assistance of a Military Staff Committee, responsible for the strategic direction of the armed forces placed at the disposal of the Security Council. This Committee will consist of the chiefs of staff of the permanent members of the Security Council or their representatives, and is clearly a continuation of the present Joint Chiefs of Staff Committee, although any member not permanently represented on the Committee may be invited by the Committee to join it. The main responsibility for the exercise of force is placed squarely on the shoulders of the Great Powers, who alone possess the necessary resources to wage war effectively.

Beyond these measures, the Charter contemplates the fostering of regional arrangements for the maintenance of peace and security and the settlement of local disputes, and the Security Council will also utilize such regional arrangements for enforcement action under its authority where appropriate. As already indicated, there is to be an International Court of Justice, constituted and functioning either by a new statute, or by a continuation or modification of that constituting the present Permanent Court of International Justice. Similarly, the clauses

relating to the secretariat are obviously modelled on Geneva experience.

In place, however, of those Articles of the Covenant relating to social activities and international bureaux, there is a separate chapter in the proposed Charter, covering international economic and social co-operation. Here it is declared to be the purpose of the organization to facilitate solutions of international economic, social and other humanitarian problems, and promote respect for human rights and fundamental freedoms, with the view of creating conditions of stability and well-being which are necessary for peaceful and friendly relations among nations. The responsibility for the discharge of this function is vested in the General Assembly, acting through an Economic and Social Council consisting of representatives of eighteen members of the organization, and elected for terms of three years by the General Assembly.

This Economic and Social Council would be empowered to make recommendations on its own initiative in international economic, social and other humanitarian matters, and to receive and consider reports from the related specialized organizations and co-ordinate their activities. It would establish an economic commission, a social commission and such other expert commissions as may be required. The Council would be provided with a permanent staff constituting part of the secretariat of the organization.

The proposals thus outlined are loosely worded and there are other questions reserved for further consideration besides the thorny one of voting procedure in the Security Council specifically mentioned. They represent a framework and not a completed edifice like the League Covenant. Within that framework, it should be possible to build a practical edifice, though in some respects the proposals are so wide that it is not easy to discern even yet the precise shape of the organization to be hammered out in due course by the drafting committee and by that public debate which, as Lord Cranborne has indicated, the Government has invited in publishing the proposals. It is essential, as was emphasized by Lord Cranborne, that the people of Great Britain and of other countries should understand the reasons for the main provisions of a peace settlement and how it came to be made, and that they should accept, and know that they are accepting, a share of the responsibility for these arrangements and for maintaining them in the future as the agreed means of preserving peace and prosperity in the world.

Conversely, it is true, as recent debates on the German problem have indicated, that whatever settlement is reached must be one which will command the support of British opinion not merely to-day but in twenty or thirty years time. From that point of view it is important to note that the proposals embody much that is common ground. They follow indeed so much on the lines of the League of Nations that at first sight it is difficult to see why the Covenant of the existing League could not be re-shaped for the present purposes. It can at any rate be said that it is proposed to utilize past experience to the full and to build on existing structures so far as possible. The scheme outlined under the Economic and Social Council should provide, for example, for continuing the work of the International Health Organization, and other technical organizations of the League.

Furthermore, the proposals meet the point on which there is now general agreement, that any system which is to be workable must take account of the special status of the Great Powers and not pretend, in the name of collective security, to diffuse the responsibility for questions of war and peace among those who could not execute the decisions. Next, they meet the argument that a system to engage the idealism of mankind must be designed to solve the great majority of questions by free agreement and without the use of force. Clearly the proposals now drafted could cover both the utilization for peace-time purposes of the regional and functional organizations established to serve the present purposes of the United Nations and provide for their effective co-ordination. There is at least a hint that the organization will ultimately address itself to the positive side of security—the elimination of the causes of war themselves by the evolution of a science of peaceful change—and it may well be that in the end the Economic and Social Council rather than the Security Council will be the important organ.

There are yet many points to be cleared up. National sovereignty still figures prominently, and with the reservation on internal causes of dispute may well be a source of danger pending the further evolution of international law or the overlaying of the conception of security on frontier lines with a natural growth of common activities and administrative agencies which make frontier changes meaningless.

Meanwhile, it should be remembered that, like the Bretton Woods and Hot Springs Conferences, that at Dumbarton Oaks stands for one of a series of conferences designed to ensure that the United Nations remain united in peace. It must not be forgotten, for example, that no machinery of security will withstand the strain of mass unemployment, falling standards of living and social and economic chaos. However excellent in themselves the proposals of the Dumbarton Oaks Conference may be, their success will depend on the sincerity and faithfulness with which the policies of the United Nations Relief and Rehabilitation Agency and of the Food and Agricultural Organization initiated at Hot Springs are carried out, and on the removal of trade barriers and the harmonization of national policies to maintain a high and stable level of employment adumbrated at Bretton Woods. It will also depend, too, on how far and thoroughly the implications of the proposals are understood by the people of Britain and of the other United Nations, and the extent to which they are prepared to make the sacrifices necessary to establish an effective organization through which the spirit of scientific inquiry can enter fields where prejudice and selfishness and the habit of judging in one's own cause have too long reigned supreme.

## SNAKES OF INDIA

**The Fauna of British India, Ceylon and Burma, including the whole of the Indo-Chinese Sub-Region**

(Published under the patronage of the Secretary of State for India.) Edited by Lt.-Col. R. B. S. Sewell. Reptilia and Amphibia. Vol. 3: Serpentes. By Malcolm A. Smith. Pp. xii+584. (London: Taylor and Francis, Ltd., 1943.) 45*s*.

HERPETOLOGISTS, especially those in India, will greet with warm satisfaction the appearance of a new book dealing with the anguifauna of the Indo-Chinese sub-region. The revision of previous work has been eagerly awaited for some years, as nothing has appeared in book form dealing with this specified area since Boulenger's "Catalogue" in 1896.

The work of revision has been entrusted to Dr. Malcolm A. Smith, and nobody better qualified could have been chosen. With his high scientific attainments, he combines the unusual distinction of having by a long residence in Siam been brought into intimate association with living snakes in their natural haunts, a distinction not usually enjoyed by writers of such books. He has made an exhaustive survey of the notes and papers that have been contributed to various journals by various writers during the last forty or so years, subjected them to a searching analysis, and corrected nomenclature where necessary. In addition he has reviewed the work of every earlier herpetologist, and incorporated the result of their researches with his own.

The first thirty-five pages of this quarto volume are introductory; the later pages up to 526 are devoted to the description of some 389 species, with useful keys to assist identification. Valuable appendixes follow dealing with the Hardwicke and Russell collections, and there is a very complete list of the bibliography on the subject.

The introduction is crowded with facts, and the information therein contained should serve to satisfy the curiosity of the most inquisitive mind. The subject-matter includes numerous anatomical considerations, evolution, classification, geographical distribution, habits, etc. Each topic is considered under a separate heading, and the facts dealt with tersely but adequately. The grain of the matter is there divested of its husk.

In the realm of anatomy, special remark is called for concerning the curious and complex system of facial and salivary glands, well illustrated on pages 12 and 13, with further remarks later in the text; also the variously disposed and mysterious system of subcutaneous glands, elaborated still further in the text under individual species, and well illustrated. All this information is entirely new, and accounts for the silence on the subject of previous authors.

Another matter now introduced to our notice concerns the male genitalia. These very remarkable twin organs have been little studied in the past, but remarks accompanied by good illustrations showing them *in situ* in their quiescent state are furnished.

There is no reference to the occipital condyle. This process, so vastly different in the lowly organized families such as *Uropeltidæ*, compared with the more highly organized, deserves special attention and may prove of some influence in the separation of families.

I have scanned the pages of this book closely, and find that no branch of the subject has received more favoured attention than another. Every matter has been most thoroughly examined and treated. The scientific man will appreciate and praise every part of the volume. The unscientific reader will find the introductory part intelligible and richly informative.

I am in accord with nearly all Smith's views and his corrections of others' work, including my own. He has very rightly rigidly observed the law of priority, which some of his predecessors have not respected. As a consequence the multiplicity of changes in nomenclature is truly deplorable. Had all previous authorities been equally meticulous, the necessity for reviving earlier names that should never have been discarded would not have arisen; further, workers in this field of zoological research would have been spared the vexation and inconvenience engendered by abandoning names with which they had long been familiar, and adopting new ones.

The substitution of *Leptotyphlopidæ* for the family *Glauconiidæ*, and of *Anilidæ* for *Ilysiidæ* will not be challenged; about the abolition of *Amblycephalidæ*, more hereafter.

At least twenty-three of the eighty-nine genera dealt with have had their names altered from those used in Boulenger's "Catalogue"! I have critically examined these, and regard the grounds for change unassailable in every case, most of them depending on the operation of the law of priority. They are too numerous to review in detail, but a few demand special remark. It has long been apparent that the genera *Coluber*, *Zamenis* and *Ablabes* (now *Opheodrys*) needed revision, and I think the changes now effected are well founded and therefore should escape alteration by future taxonomists.

The genera *Ptyas* and *Elaphe* have been revived at the expense of *Zamenis* and *Coluber*, and there has been some reshuffling of other species. The restoration of *Ptyas mucosus* to generic rank will not be contested. I had hoped to see this species treated somewhat differently. It is unique in the arrangement of its scale rows, of which seventeen in the anterior half of the body are reduced to sixteen shortly behind. This reduction is effected by the disappearance of the uppermost costal row on the left side. A similar reduction of scale rows, from seventeen to sixteen, and by the same method, occurs in all the species of *Zaocys*, but in the neck instead of the body. This, together with other very close affinities, would warrant the abolition of the genus *Zaocys* and the inclusion of its species in the genus *Ptyas*. The affinities of *korros* and *mucosus* are not so marked as those of *mucosus* with the species of *Zaocys*, and warrants the exclusion of *korros* from *Ptyas*. *Simotes*, separated from *Oligodon* on false claims, has been very properly suppressed.

*Ahaetulla*, a revival on grounds of priority, embraces and supersedes the two genera *Dendrophis* and *Dendrelaphis*, separated on insufficient grounds.

The revision of the sea-snakes and the amended classification constitute a great advance. The arrangement of this group is now intelligible to all, where previously it was in part unintelligible even to experts. The bewildering confusion that previously existed has been swept away and order established where chaos reigned. The basis on which the classification now stands is sounder than ever before. The genus *Distira*, based on false premises, has been abolished, and eighteen species recognized by Boulenger have been placed with *Hydrophis*, which, in spite of this increase, now only numbers fifteen species where Boulenger recognized twenty-two. The recognition of the genera *Kerilia*, *Præscutata* and

*Microcephalophis* and their isolation from *Hydrophis* will receive general approval. This good work might have been further extended, and genera multiplied at the expense of *Hydrophis*.

*Hydrus platurus* was the name fixed by international approval some twenty or so years ago for the species now designated *Lapemis platurus*, and it will be regretted that after such an authoritative ruling the generic name has not been upheld.

Any disturbance of the admirable treatment of the family *Colubridæ* by Boulenger is to be deprecated, except in the ranks of genera and species. Such, for example, as the elimination of the proteroglyphs from that family, and their elevation to the dignity of independent families. I regard this as unnecessary. To be consistent, the opisthoglyphs deserve similar treatment and equal rank, which is not conceded to them.

Again, the association of the aglyphous African *Dasypeltis* with the opisthoglyphous Indian *Elachistodon* and their inclusion in one family will be severely criticized. I prefer Boulenger's views. If this arrangement stands, each deserves to be placed in an independent sub-family.

The abolition of the family *Amblycephalidæ* is a bold departure from previous views. The six species that used to figure in that family have now been deposed from the exalted position they occupied above the family *Colubridæ*, and are placed on a low rung of the *Colubridæ* ladder. *Haplopeltura* retains its title, but *Amblycephalus* has been superseded by its earlier title *Pareas*. The dentition of the latter is distinctive, and differs from any species of *Colubridæ* that I have dissected. The cephalic lepidosis is remarkably distinctive, and also differs from that of any other Colubrid known to me.

The generic name of the cobra should be altered to *Naga*. It was clearly the intention of Linnæus to attach to it the name by which it is universally known to the natives of India—"nag" (pronounced narg). It is probable that this information was conveyed by letter and that he mistook the 'g' for a 'j'. *Naja*, and still less the *Naia* of some authors, have no meaning. Under the amended and more elastic rules of nomenclature referred to on page 33, such an alteration would be permissible. The suggestion might well be referred to the next session of the International Committee of Nomenclature.

No remark as to location accompanies the list of Russell's types on page 531. I examined them in the Museum of the Royal College of Surgeons. Their transference to South Kensington would make them more accessible, and they would fittingly rejoin Russell's collection of skins already there.

I am glad to note that doubts raised as to some of Beddome's localities have been upheld, and in consequence the spurious localities rejected, and habitat appropriately amended, as instanced in the case of *Oligodon splendidus*.

The map at the end of the book would be more useful if the boundaries of the tracts had been demarcated.

The artist deserves unstinted praise for the excellence of her work. The figures depicting the dorsal and ventral markings especially are very beautifully executed. The multiplication of such figures would have been advantageous.

Dr. Smith has quoted me extensively, and paid a very generous tribute to my work. He has also corrected me freely and deservedly. The fact that in compiling his book he has had close access to the national collection at South Kensington, with the many types it contains, and also a library to consult comprising the whole of a voluminous bibliography combine to make his opinions far more authoritative than mine.

Finally, a few discrepancies have been noticed. *Dasypeltinæ* should be excluded from the synopsis of the sub-families of *Colubridæ* on page 114 so as to agree with the family status on page 403. *Oligodon subgriseus* on page 531 should read *O. tæniolatus* to agree with page 223. *Callophis trimaculatus* on page 532 should read *C. melanurus* to agree with page 420.

F. WALL.

# CEREALS AND HISTORY

**Six Thousand Years of Bread**

Its Holy and Unholy History. By H. E. Jacob. Pp. xv+399+8 plates. (Garden City, N.Y.: Doubleday, Doran and Co., Inc., 1944.) n.p.

IN describing the history of bread, Mr. Jacob has, in effect, attempted to explain the political and economic history and social structure during the eras of their political ascendancy of ancient Egypt and Greece, the Roman Empire, Europe and the United States in terms of religion and of the cultivation of cereals. The result is, however, too simple to be of much interest to historians, and its value for lay readers, for whom it is obviously intended, is reduced by the paucity of dates.

Generally speaking, bread is made only from wheat and rye, and it is with these two cereals that the book is therefore chiefly concerned. A chapter is, however, devoted to maize, which was introduced into the eastern Mediterranean by the Venetians and was then widely planted in the Near East by the Turks, to whom its ease of cultivation and rapidity of growth made a great appeal. These cultural characteristics were responsible for its spread in the seventeenth century into south-eastern Europe and, in the western hemisphere, allowed the colonization of North America to proceed much more rapidly than would have been the case had wheat been the staple cereal. In southern Europe, the initial popularity of maize, which soon became the staple food of the poorer classes, declined when its association with pellagra was recognized in the nineteenth century; in the United States, however, the consumption of a mixed diet prevented the appearance of pellagra, and it was not until 1900 that the American taste changed and wheat was preferred to maize flour.

Mr. Jacob suggests that in the early days of human history new inventions would have been quickly forgotten had they not been sanctified by the local religion, but when the barbarian invasions of the Roman Empire brought the Nordic pagan religions into conflict with Christianity, the Roman agrarian techniques were lost in the resulting spiritual confusion, as a result, the Middle Ages became an era of ignorance and famine. Religion itself is shown to owe much to agriculture. Thus the cults of Demeter in Greece in the seventh century B.C. and of the maize god in Mexico in the fifteenth century A.D. were but recognitions of the importance of cereals in the food economy, while, in the Christian religion, with its controversies over the doctrine of transubstantiation, bread acquired a spiritual rather than an economic significance. Once the concept of personal freedom had been developed (a concept absent

from ancient Egypt), the coexistence of a stable political structure and of an impoverished peasant class was impossible, and the expropriation of the peasants is considered by the author as an important causal factor for the decline of the Roman Empire, for the European peasant wars of the Middle Ages and for the French Revolution. The importance of an adequate food supply (of which cereals and potatoes form the basis) in the waging of wars is further emphasized by reference to the American Civil War, the Napoleonic Wars, the War of 1914–18 and the present War.

The author points out that after the discovery of agriculture and the invention of the plough by primitive man, no important scientific agricultural advancements occurred until the seventeenth and nineteenth centuries A.D. The developments of the seventeenth century took place in England and consisted of the invention by Tull of a mechanical plough equipped with a sowing device and the evolution by Viscount Townshend of a four-year crop rotation. In the nineteenth century, developments in the United States were concerned with the technical improvement of agricultural machinery, whereas in Europe the work of Liebig and Pasteur together laid the foundations of agricultural chemistry. During his life-time, Liebig's work was unknown in the United States, and it was not until 1935, when soil erosion assumed immense proportions, that the Americans adequately realized the importance of a biological approach to the problems of soil cultivation. Mr. Jacob emphasizes that the range of climatic conditions within which wheat can be cultivated has been greatly extended by selective wheat breeding and by Lysenko's discovery of vernalization; but his cursory accounts of Mendelian heredity and of vernalization do not accord with the economic significance he rightly attaches to these two processes.

The specific history of milling and bread-making is scattered throughout the book, and is treated in rather a general and cursory way. In the case of reductional roller milling particularly, more detail concerning the various operations could advantageously have been included. The invention of mechanical mills by the Romans, and of windmills in the Middle Ages, and at the end of the eighteenth century the use by Evans in the United States of steam as the source of power for all the milling operations are regarded by the author as landmarks in the history of stone-milling. The principle of reductional grinding was first introduced in 1760 by Malisset, and the superior digestibility of the resulting flour, which unlike that hitherto produced was relatively free from finely divided bran, was soon recognized by Parmentier. It was not, however, until the invention of the roller mill in 1830 that reductional grinding and the consequent production of white flour became universal.

Mr. Jacob points out that bread was first made by the ancient Egyptians and, until the Middle Ages, when the miller became a countryman and the baker a townsman, milling was performed by the bakers. In the Middle Ages, the scarcity of grain resulted in the baking of substitute breads many of which had no nutritional value, while just prior to the French Revolution the use of potato flour in bread-making was investigated by Parmentier. After the Revolution, the consumption of rye bread gradually declined throughout Europe, but no important developments in bread-making occurred until about 1920 when the mass production of bread began. The enrichment of white flour with vitamins and minerals in the United States—surely a landmark in the history of bread—is only discussed very briefly.

Mr. Jacob has presented an interesting historical account of cereal cultivation, and his book should stimulate among general readers an interest in anthropology and history. It is unlikely, however, to arouse much enthusiasm from cereal chemists.

Norah J. Watts.

## REINFORCED CONCRETE STRUCTURES

**Reinforced Concrete Simply Explained**
By Dr. Oscar Faber. Third edition. Pp. 80. (London: Oxford University Press, 1944.) 6s. net.

**Simple Examples of Reinforced Concrete Design**
By Dr. Oscar Faber. Third edition. Pp. 84. (London: Oxford University Press, 1944.) 6s. net.

The fundamental ideas behind the design of reinforced concrete structures are simple and can be stated in a few elementary formulæ. The author of the present volume, which appeared first in 1922, aimed at producing a simple book on the subject which could be understood by comparatively non-technical readers, and the appearance of a third edition at the present time is evidence of the success and usefulness of his effort. The well-known "Code of Practice" for reinforced concrete has been adopted, with modifications, by the L.C.C. since the appearance of the first edition, and the present issue has been brought into line with the existing regulations of that body. The subject-matter covers the treatment of beams, columns and slabs, the shearing resistance of beams, and a discussion of the materials used.

Generally, the presentation fulfils its purpose, but there are occasional places where further revision would be valuable; for example, the statement on page 12, "When steel is stressed in tension it elongates and the amount of the elongation depends directly on the stress, on the length of the bar and on the material (This is called Hooke's Law)". The diagrams, too, vary considerably in style, and the general appearance of the book would be improved if they were made uniform.

These, however, are comparatively small points, and this introduction to a subject on which so much has been written has served, and will continue to serve, a very useful purpose.

The present edition (the third) of the companion volume brings the examples of calculation into line with revised official regulations necessitated by the development of materials and of design technique. The structures dealt with are intentionally simple, but they are well graded. The six examples are a circular water tank, a square tank, a floor slab and beams, a warehouse floor on concrete columns, a retaining wall and a water tower. The calculations are set out in detail, and reasons are given for the various steps and decisions taken. Perhaps one of the most useful features is the insertion of comments on practical constructional details drawn from the author's wide experience; this makes the examples very much more than mere arithmetical exercises.

The book is already well known from the earlier editions, and there is no doubt that the present generation of students and young designers will welcome this revised edition.

## Clowes and Coleman's Quantitative Chemical Analysis

An Intermediate Text-Book. Revised and edited by Dr. Julius Grant. Fifteenth edition. Pp. viii+557. (London: J. and A. Churchill, Ltd., 1944.) 21*s*.

ALTHOUGH this edition is sixty pages shorter than the previous one, published in 1938, the new editor states in the preface that much new material has been incorporated and that deletions are confined to doubtful or redundant material, all the classical methods being retained. The whole text has been carefully revised, and the new parts represent standard modern methods which should be described in such a work.

Clowes and Coleman's book, which was first published in 1891, is, so far as the reviewer knows, unique. It is at the same time a student's manual, providing a carefully graded course, and giving all the detail necessary for the successful procedure of the analysis, and also a very useful reference book to practical analysts. It covers a much wider range of subjects than most books of its size, and includes a number of sections on such subjects as water analysis, foods, oils, fats and waxes, soap, organic analyses, gas analysis, and some physico-chemical determinations such as vapour densities and molecular weights. The reviewer has often followed the book in past editions in carrying out analyses with which he was not very familiar, and in all cases has found the methods described satisfactory and accurate. The book is full of useful practical laboratory hints, and a good index makes it easy to use. There can be little doubt that in its modernized form, in which important and well-tried new methods find a place, the book will continue to maintain its deserved popularity. The paper, printing and binding are all very good, and the way in which it opens easily will be appreciated by workers at the laboratory bench. The book is recommended to students, teachers and practical analysts.

## Cattle at the Crossroads

Broadcast Discussions in the Home Service of the B.B.C. on Cattle Breeding from the Series 'Farming Today'. Pp. 60+8 plates. (Worcester: Littlebury and Co., Ltd., n.d.) 5*s*. net.

A SERIES of six broadcast discussions on the breeding, rearing and management of cattle in Great Britain is here printed, almost verbatim, from the original script. Designed principally for the interest and information of the small farmer, each talk is in the form of a dialogue between an expert in the field discussed and an eminent practical farmer, with the chairman (Mr. W. S. Mansfield) guiding the discussions and linking them together.

The speakers were drawn from widely different areas of the country, and the complexity of the cattle industry in Britain is thus well illustrated. Points touched upon—all very briefly—range from mastitis to the effects of the bull licensing scheme, and from hill cattle to artificial insemination. Problems considered are mainly the immediate ones of dairy farming and that of the post-war source of animals for beef production. The viewpoint is that of the producer: there is little consideration of the effect of government policies, and less of marketing arrangements and consumer-preferences.

The title is apt because the average quality of our milking cattle is poor, and greater efficiency will be required after the War. The discussions show how greatly the prospects of improvement depend upon a proper understanding by breeders—the majority of whom are not specialists, but mixed farmers—of their objectives.

## Man Studies Life: the Story of Biology

By G. N. Ridley. (Thinker's Library, No. 97.) Pp. x+109. (London: Watts and Co., Ltd., 1944.) 2*s*. 6*d*. net.

AMONG specialists it is a common fallacy that, to obtain the interest of the general reader in a new subject, the introduction must consist of a potted version of the whole study under consideration. Usually, after reading one of these potted works, the unfortunate layman has to sit back until he has recovered from the pangs of mental indigestion; and when he surveys this miserable scene, the educationist once more sadly shakes his head and murmurs: "Too much attempted; too little done!" "Man Studies Life" is such a work. The author set out to write a book which badly needed writing—the story of the growth of biological science throughout the ages. In trying to condense that story into a slender volume in which almost every outstanding figure in biology is mentioned, Mr. Ridley has succeeded in producing only a disconnected series of bits and pieces which would be of doubtful value even to the most intelligent layman.

There are few diagrams, one of which is confusing, while another, a time-chart of science, would be extremely valuable if it were more directly related to the text. The whole appearance of the book is too drab to be inviting, a failing which "conformity with the authorized economy standards" does not wholly excuse.

If this book were expanded to four times its present size and presented in a brighter battle-dress, it would be received with avidity by many non-specialist readers. T. H. H.

## Applied Electricity

By A. W. Hirst. Second edition. Pp. xii+367. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1944.) 17*s*. 6*d*. net.

THE demand for this type of text-book has enabled the author to make some useful additions, particularly chapters on power distribution and thermionics. A chapter on materials gives useful notes on a subject which is too often glossed over, although pivotal in industry. In general, the text is adequate for the new Section B in the A.M.I.E.E. examination, and for the Engineering Cadet course. The treatment is everywhere clear and to the point, except in those aspects to which the reviewer objected in the first edition, namely, the relevant torque in a rotary machine is not on the conductors but on the iron, and the confusion between the terms 'electromotive force' and 'potential difference' (p. 70). While one can properly speak of the 'counter-electro-motive-force' in an inductance or condenser (better 'capacitor', according to the latest B.S.I. Glossary), because of the storage and delivery of electrical energy temporarily transformed, one simply cannot accept in these days 'counter-electro-motive-force of a resistance'. When the author states a Kirchoff Law as "the algebraic sum of all the E.M.F.s in any closed circuit is zero", what would he say of a uniform closed conducting ring embracing an alternating magnetic field? There is certainly a single Faraday electromotive force, but there is no potential difference that can be measured anywhere. L. E. C. H.

# ADVENTURES IN PHENOMENOLOGY

By F. I. G. RAWLINS

THE year 1938 marked the end of two lives rich in achievement, those of Edmund Husserl and Samuel Alexander. Not only so, but 1859 witnessed the birth of each of them. So far as Great Britain is concerned, it is scarcely possible to imagine a greater contrast between two contemporaries in regard to influence and knowledge of their works: Alexander, widely recognized and read; Husserl, almost unknown, except to the few. Perhaps it is needless to pursue this matter further, except to remark that Husserl has been but little translated into English, and that in the original German his style, but more particularly his thought, is difficult and complex to a degree rarely encountered even in the *Geistliteratur* of Continental philosophers and psychologists.

All the more, therefore, is it an occasion for deep satisfaction that in gratitude to the great thinker of Freiburg, some of his old students, admirers and critics, who now hold distinguished positions themselves, should have combined to contribute in English a volume of philosophical essays in his memory, under the editorship of Prof. Marvin Farber of the University of Buffalo*. At the end, they have included a fragment by the master himself (in German), dealing with the origin of space. It is a precious little thing, vivid and informal, written in two days during the spring of 1934. We will leave it at that. Our concern is more with those who in this book have laboured, with considerable success, to bring Husserl before the English-speaking world of scholarship. But lest it should be imagined that his genius has meanwhile become sterile, or his flame extinguished, be it remembered that a regular publication entitled *Philosophy and Phenomenological Research* exists, devoted to the furtherance of his doctrines. In the United States, too, the presence of many of his disciples at the head of philosophical faculties is a testimony to Husserl's power as a teacher.

To trace the pattern of his thought, it is well to recollect that the nineteenth century produced a heavy pressure by scientific facts to obtain possession of the domain of 'intrinsic requiredness', a terrain necessarily strongly defended by the philosophers, but—on balance—favourable to attack. Husserl knew this only too well, and initiated counter-measures designed to focus attention upon 'things themselves' rather than upon such doubtful devices as learning and evolution to explain logical principles. This urge to basic contemplation of an object is extraordinarily difficult to implement: it is akin to an art. In any event, it is the activity which for Husserl constituted phenomenology. The word itself, however, appeared in English long before that, seemingly towards the end of the eighteenth century, when it was used in a far more naïve sense by Robison. Moreover, the present context has little in common with the term occasionally found in the theory of models, beloved of nineteenth century physics.

Phenomenological observation is more than straightforward attention; it is essentially reflective. The difference is between description of objects *per se* and that of *intentional* objects. Generally, observation within the natural sciences is 'simpliciter', rather than of the extreme kind demanded by Husserl. It is important to realize this in view of the way in which phenomenology exhibits certain parallels with Aristotelianism, and therefore with the concepts of substantial form and matter as the schoolmen knew them. For us to-day, the fear of introspection may go too far: clearly if the process leads to an arbitrary, even capricious, dichotomy between genuine and spurious reactions, then it is reprehensible. But nobody can seriously discard it in so far as it concentrates our mental powers upon things themselves. At least it formed at one time a fair part of the psychologist's method, even if to-day its findings are considered as a creed outworn.

We have now arrived at the threshold of Husserl's early battles, namely, those with the manifestations of 'psychologism' in its various forms. This arch-enemy, as he conceived it, is a tendency to make reason depend upon something other than itself. Phrases like 'the group mind' or 'the mind of a certain cultural epoch' are suspect from this point of view. Reason is reason *pure et simple*, and to assert otherwise is to forfeit any claim to be on the side of the angels. Years ago, Koffka saw this hazard clearly enough, and with characteristic courage assembled all the forces of the *Gestalt* psychologists to vindicate their integrative principles at the crucial point. And on the whole, not unsuccessfully. In fact, 'once bitten, twice shy'.

Can it, however, be said that, as the history of thought through the ages is unfurled, any well-established philosophical system as such has attained even partial victory over the evils of psychologism? A reply to this question is one of the most remarkable passages in this collection of essays. The perennial philosophy is found to face up to the problem squarely, and starting from Plato's onslaught upon the Sophists, to grapple with it. Recalling the present-day interest in the revival, in modern form, of scholasticism, this inherent capacity of Aristotle, St. Thomas Aquinas and their followers to provide a contingent for Husserl's army is extremely significant. His radicalism, issuing in a fierce striving for a 'presuppositionless' philosophy, is enough to entitle him to a high place among the candid friends of learning, be they of the world or of the cloister. Indeed, the word 'psychophysics' has come into use now, a study partially anticipated by Brentano, when he introduced his conception of intentionality of consciousness. He tries to distinguish between physical and psychical phenomena by ascribing to the latter a species of vectorial property. The details are rejected by Husserl; but the suggestion is intriguing on account of its obvious importance for theories of the numinous on one hand and of the psychological view of causality on the other. It was G. E. Müller who once remarked that contact with psychological problems was a pre-condition for any final acceptance of a system of physics. At this stage it is just as well perhaps that not everybody is irrevocably committed to a completely rigid necessitarianism in human affairs.

The question now is whether the *supposedly* real is *really* real. This is almost, if not quite, the fundamental connexion between phenomenology and epistemology. In other words, what, if anything, does the 'reality-phenomenon' tell us about 'real' reality? A number of criteria can be advanced in favour of the reality-phenomenon, of which the following are examples, not necessarily complete:

* Philosophical Essays in Memory of Edmund Husserl. Edited by Prof. Marvin Farber. (Published for the University of Buffalo.) Pp. viii+332. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1940.) 22*s*. 6*d*. net.

(1) Readiness, (2) persistence, (3) the perceptual periphery, (4) boundaries in concrete objects, (5) independence, (6) resistance, (7) agreement. A conservative view would suggest that there is at least a measure of reality behind the reality-phenomenon; but this is not to assert that complete identity can be expected in the case of sense perception. It may well be that some kind of equivalence is the most that mankind can achieve.

Phenomenology has already been likened to an art. This resemblance receives new force from the concept of 'horizon' which Husserl first evolved in 1913. To explore the horizon implies a move away from 'under one's nose' to a broader context. In *Gestalt* terminology it is a drive for integration; in poetry the psalmist's cry, "I will lift up mine eyes unto the hills, from whence cometh my help". Again, horizon simulates a frame, a hand outstretched towards articulation and a recognition of wholeness. But there is no need for such a frame to be irksome; ever new horizons appear as we shift away from the centre, a type of expanding experience. Teleological metaphysics invoked 'art' to couple together object and human situation: Husserl substituted 'constitution' and, as a result, found himself in an atmosphere of intense radical idealism.

A difficulty, apparently inseparable from much of this activity, arises from the temptation to assume that its penetrating light can be cast upon problems of theoretical physics in their present form. At the moment, this is an error. The contrast is mainly between logical empiricism and phenomenology, with little effect outside what the men of science would commonly call philosophy. Logical empiricism, flowing from the Sophists, continues in its historic course alongside, but separated from, the waters welling up from Plato and Aristotle and finding rest in Descartes and Leibniz. In a way, these latter seem nearer to Husserl. However, the natural sciences to-day are not altogether enamoured of Cartesianism, and a natural question to ask is whether any bridges exist, or whether they have already been blown. Two signs look hopeful (at least as regarded by those who believe it not impossible to retain and even to reinforce the solidarity of knowledge); one is the conviction, almost universally held, that Greek geometry is not *a priori*, and the other is the progress made in recent years in symbolic logic. A full grasp of these disciplines is only possible by liberating problems of origin from that mental habit which confuses mind with nature. Clearly, what is involved is no less than the whole structure of history, a position which some other thinkers have adopted, if not with quite the same ruthlessness as Husserl. It is interesting to notice how his radicalism pervades everything he does; it is with him much more than a mere *façon de parler*. For example, he rejects the classical and more traditional concept of a 'root', in favour of the Empedoclean term. This latter is altogether more primitive. It connotes a rough, shapeless thing, rather than the perfect form of mature growth. This is potency—and teleology—with a vengeance; not the ideal—though that is what is sought—but the possibility of life and development. In this is displayed the true historian, and simultaneously the need for 'intentional history' if phenomenology is to live.

Paradoxically enough, however, Husserl produces an analysis of the origin of mathematical physics—without recourse to actual historical inquiry as we know it—by means of his intentional-historical method; an example of the lengths to which empathetic treatment can go.

So far, phenomenology has appeared mainly in the company of the exact sciences; this, however, is far from the limit of its powers. We are faced with what it has to say about the social sciences, art, and in general, the immediate activities of mankind. Later on, however, it will be needful to return to mathematical symbolism, seeking therein the bond between Husserl's earliest work and our hopes for the future. Meanwhile, he strives to appreciate to the full the problem of the *alter ego*. His way of thinking can best be illustrated by a remarkable passage in which he 'dares' phenomenology to enter the dark corners of other people's experience and not to run away, adding that fear of the dark is only for children in philosophy, expecting at any moment to meet the bogey of solipsism. One cannot resist putting this side by side with the Pauline care for those of (spiritually) tender age, offering them milk rather than meat. Thus, as in Corinth long ago, so in Freiburg, the master will demand no more of his followers than he thinks they can bear. Even Leonardo da Vinci confesses to terror of a dark cave when searching for prehistoric bones, but overcoming his emotion, continues his quest and achieves his object. In the abstract, Husserl did much the same in his groping after a phenomenological basis for the social sciences. Above all, he is not prepared to immunize the physical world against mankind.

A natural step from here is into the realm of art. A measure of æsthetic purity involves appropriateness in that there must be purposeful accuracy for the expression of feeling: greatness in a work of art, however, demands profundity in making manifest the depths of being previously experienced. Some years ago Birkhoff evolved his æsthetic formula and by its means gained considerable success in objective judgment relating to patterns, vases, music and poetry. His method was restricted almost entirely to the formal domain of art. Later, the present writer attempted an application of *Gestalt* principles to paintings, based essentially upon energetics. This treatment tried to penetrate the fringe of the connotative region. Phenomenology shows a certain divine discontent with the ontological in its more naïve forms, very roughly analogous to the tendency of æsthetic experience to turn inwards upon itself. Nevertheless, though art may be more imaginative than truly inventive, there is an undisputed place for what Samuel Alexander has so well called 'constructive excitement'. Rilke's "Sonnets to Orpheus" contains the words "He binds with more cunning the boughs of the willows to whom the roots of the willows are known". This applies not only to the poet and to the philosopher but also to the man of science. In the early stages of knowledge trial and error may be the only way of making progress; later, a comprehensive grasp of 'requiredness' may enable the whole to be rapidly completed. One gains the impression that Husserl himself no less than those who write in support, or in criticism, of his doctrines are resolved to avoid the cruel folly of conducting a blind man into a pitch-dark room, to look for a black cat that isn't there.

For something like a couple of centuries physicists have worked away without any apparent regard whatsoever for metaphysics. Philosophers, for their part, have not failed to notice the impressive strength of scientific fact arrayed against their own interna conflicts of opinion and so forth. But they are con-

tinually re-examining some of their systems and stressing the need for yet another consideration of the relations between science and philosophy. Phenomenology has not escaped, but has been provisionally eased out a little on a frame of neo-positivism. But the source of inspiration is still Husserl himself. Even his omissions and denials possess importance. For example, for him experience is immediately social in a limited sense, but to say "that one's own experience contains the actual experience of others as real, immanent elements" would be inacceptable by him.

Already in this review a mild defence of introspective methods in experimental psychology has been offered. In virtue of certain materialistic approaches to phenomenology which have been made, it is unavoidable that they must become attractive targets. But their very weakness was one reason among several which impelled the then youthful Wertheimer to heroic efforts to end or to mend psychology as it then was. The result was the founding of the *Gestalt* concept. Ironical as it may be, perhaps intentional-history is asserting itself within the sphere of embryonic research.

That phenomenology is an art, a methodology and even a way of life all at once, should not blind us to its main characteristic as a mental construct suitable for dealing with the Universal rather than with the Particular. It is therefore not surprising that some of Husserl's followers should be attempting something like a metaphysics of the factual element. One such system is sketched in the work now before us. It is distinguished for its moderation and resilience. At least, it is held, mankind can express a desire to understand the world without postulating that it is wholly 'intelligible'. It will suffice for the purpose if the world is 'fact', but not 'mere fact'. The significant point is contained in the attitude that slavery to fact may be quite as oppressive as that to 'authority' and the rationalizers. The latter types of bondage produced a series of explosions too well known to need recapitulation here. But a decision in advance never to venture outside 'mere fact' (if only, so to say, for fun, to see what happens) is as dyspeptic as it is unenterprising. Metaphysics is not prepared to come to terms finally either with 'authority' or with 'mere fact', if only because, should the world be meaningless, so would metaphysics be too. Doubtless there will be some dissent from much of this, but it is refreshingly robust all the same. One should not read these essays in and around Husserl's life and influence unless reasonably shock-proof. Their charm —which applies to one and all—resides very largely in an engaging humility and a certain lack of the doctrinaire, ready to 'take it all back' if something better can be found.

A contribution entitled "Men and the Law" is included in the collection. At first glance it would seem to have little to do with phenomenology. But it is followed by another, the theme of which is symbolic logic. The juxtaposition of these two articles was a happy thought, for between them they supply something very valuable indeed. Briefly, it amounts to this. The law says *yes* or *no*. It is not directly concerned with the vast majority of the events of daily life, which fall well within the excluded middle. Its power is of another kind. Now mathematicians are intent upon the quest of finding a place for *possibility* in symbolic logic, as 'objectivized' by Hilbert's quantifier ($\exists x$). Is it at least conceivable that, far ahead, some light will come from this quarter to illuminate the very practical twilight subjects like rheology and, more generally, the applied sciences? A philosophy of the latter is awaited with some impatience for regions in which academic simplifications do not, and cannot, hold, and wherein 'facing the facts' is almost literally all that can be done.

So now, Prof. Marvin Farber and his colleagues bring their tribute volume to an end. Poured forth in honour of a master mind, their libations leave a most gracious and lasting impress, as they trickle silently away.

# ESTABLISHMENT OF VEGETATION ON COAL TIPS AND OTHER SPOIL MOUNDS

By J. W. B. SISAM
Imperial Forestry Bureau, Oxford
AND
DR. R. O. WHYTE
Imperial Bureau of Pastures and Forage Crops, Aberystwyth

SPOIL mounds of varying type and composition are the inevitable end-product of many mining and manufacturing operations. Anyone familiar with the Black Country of England or the mining areas of South Wales, to cite two important examples, well knows how the countryside can be disfigured by these tips. Under natural conditions considerable time may elapse before even a coarse grass or scrub vegetation becomes established on such material, and then the result is of little æsthetic or economic value. While in the past a certain amount of work has been undertaken locally in reclaiming tips of various kinds, usually through afforestation, such programmes have been limited in scope and difficult to maintain. It is only recently that there has been any widespread interest regarding the vegetation of spoil mounds by artificial means, with or without preliminary levelling, in order to improve the landscape, amenities and living conditions in the districts concerned. It is the purpose of this short article to indicate how knowledge on the ecology of pioneer vegetation, both forest and grassland, can be applied to this particular problem, and to suggest methods of establishing a vegetation cover on what may appear to be a not particularly promising medium.

In Great Britain, the industries responsible for spoil mounds include coal-mining, quarrying for iron and other minerals, and the manufacture of chemicals, pottery and glass. The vegetation of the tips and general waste material from these industries has been referred to in the reports of the Scott and Kennet Committees, and is receiving the attention of several Ministries, of local planning organizations such as the West Midland Group on Post-War Reconstruction and Planning, of local authorities such as borough councils in South Wales, and of the industries themselves. The problem is also being studied in the United States, South Africa and Germany.

When once the planning authority has decided on the general purpose of the reclamation, whether for amenity purposes (landscape improvement and provision of parks and recreation grounds) or for yielding an economic return, it becomes the task of the plant ecologist and the soil specialist to decide which species

of trees, shrubs, herbage or other plants are adapted to this rather abnormal environment, and what method of establishment would be most efficient for the purpose in view. Surveys are necessary to determine the degree of weathering of spoil material, the nutrient or toxic status of the forming soil, the soil moisture and degree of drainage within tips, the surface temperature and the degree of erosion and soil-wash. The problem of air impurities in districts still in active production must also be considered.

It is probably correct to say that the establishment of grass swards should be attempted only when levelling can be done. If the cost of such an operation with modern mechanical equipment is not prohibitive, and land adjacent to the tip is available, the ultimate creation of pastures or parkland can be visualized. The establishment of grass can be greatly accelerated if a covering of six to nine inches of soil or a compost made from town waste can be provided, but it should be possible to establish certain types of grass even on the crude tip material after a certain amount of weathering has taken place, especially if the weathered surface layer on the tops of the mounds is carefully preserved during levelling.

If soil is available, the usual technique of establishing grass on poor soils can be adopted, starting possibly with rape and turnips that can be grazed with sheep, and following with a grass-legume seeds mixture composed according to local conditions and requirements. Direct turfing is also possible, particularly in the formation of bowling greens.

If soil is not available, it will probably be necessary to use species with very low fertility requirements, not generally used for agricultural purposes. Surveys of natural revegetation made by botany students will provide useful information for this work. There are indications that grasses requiring low fertility such as *Aira cœspitosa*, certain species of *Agrostis*, and certain weeds could be established, and it may become necessary to commence the production of seed of unusual plants for this purpose. Lupins are important legumes that can be grown for increasing the nitrogen content of the soil. The non-palatable species are generally used, but it is desirable to test the sweet varieties, as these could be grazed at the appropriate time, and the soil would thus gain considerably from the sheep droppings. Unorthodox methods such as the spreading of mixtures of root or rhizome cuttings of bracken or *Agrostis* may be applicable in certain circumstances. The ultimate aim of all this work must be to improve the organic matter content and nutrient status of the soil as rapidly as possible, up to a stage when the establishment of secondary and superior species with higher fertility requirements can be attempted.

The creation of market gardens and allotments on tip soil is dependent upon the availability of organic manures. If stable manure or similar material can be obtained, good crops of vegetables can be expected, and have actually been obtained on the tops of coal tips.

In many cases, however, tree planting will be the method adopted for spoil-mound reclamation; the cost of levelling may be prohibitive, or the general landscape plan may require the establishment of plantations for timber production or the planting of individual trees in parkland development on levelled or partly levelled tips. Here the general principles of the ecology of pioneer vegetation will again apply, although this aspect of the subject raises a number of special problems.

The choice of tree species, the size and quality of the planting stock, and the method of planting to be used can be decided only after a careful study of the site. Waste materials are extremely variable in composition and rate of weathering, and species that do well on one site may not do so on apparently similar sites; each case must be dealt with on its own merits. Mention has already been made of the site factors that require to be surveyed; where possible a chemical analysis should be made of the constituent material of the tip before any reclamation work is undertaken.

Old, well-weathered spoil mounds, particularly those consisting of easily decomposed materials such as certain shales and fire clay that has been burnt, are readily covered with natural vegetation and should offer little difficulty in the establishment of trees. On the poorer sites, where the material is largely unweathered and sterile, it is of the greatest importance to improve the humus content and moisture-retaining capacity of the soil as rapidly as possible. The first trees to be planted on these sites should have the characteristics of true pioneer species—low nutrient requirements, a vigorous and penetrating root-growth, and the ability to build up the organic content of the surface soil through the annual fall of leaves and other debris. Species of willow, birch, poplar and alder are useful for this purpose.

Best results may be obtained if the trees are planted with their roots in a ball of earth, and such treatment is essential if species with more exacting site requirements are used. In general, it is recommended that the planting stock be 1-year transplants not more than 2 ft. in height, although poplars may be up to 5 ft. high; the plants used should have a well-developed fibrous root system and should be planted to the same depth as when taken from the nursery. They should be spaced at about 5-ft. intervals and left to form canopy before thinning. Poplars have been successfully established on a fairly well weathered tip of shale and clay by placing cuttings in holes 12 in. deep, made with a crowbar, and consolidating colliery slag around the cuttings. The only subsequent treatment was the application of manure to the base of the saplings at the end of the first year.

If feasible, a new tip may usefully be covered with a layer of soil, and the use of 'over burden' from sand quarries has been suggested for this purpose. The danger of drought in the summer, due to lack of contact with sub-soil moisture, can be counteracted by placing some peat in the planting hole. Alternatively, if the tip has weathered for some time and bears a skin of coarse grass over unweathered material, the turf removed for purposes of tree-planting should be inverted, placed in the planting hole and covered with fresh soil. Moisture conditions will be improved as the turf gradually rots and forms a humus layer. In addition, the sowing of common lupin seed in the inverted turf some time before the trees are planted will help to increase the available nitrogen in the soil. Gorse, broom and alder are also valuable as nitrogen fixers, and, in addition, provide shelter on bare, exposed sites if established before the young plants of the main crop are put in. As site conditions improve, species of greater economic value, having higher fertility requirements, may be used. Among the tree species that have been recommended for use on spoil mounds in Great Britain, in addition to those already noted, are mountain ash, elder, wild cherry, wych elm, hawthorn, laburnum, sycamore, ash, Austrian pine, Corsican pine, Scots

pine and European larch. Of the conifers, Corsican pine is particularly recommended, as it is not exacting in its requirements, stands up to smoky conditions, and thrives on a low rainfall.

Apart from soil conditions, the choice of tree species may be limited owing to exposure of the site to wind and insolation, especially at high elevations. In exposed situations, where shelter is required at any cost, alder, wych elm, thorn, elder, willow and stout birch plants have been recommended. The conifers, Sitka spruce and Scots pine, are suited to planting at relatively high altitudes. On exposed sites it is important that the planting stock be not too large in order to avoid damage by wind before it becomes properly acclimatized.

Air pollution by certain gases may prevent the establishment of any kind of vegetation, while with other forms of pollution, such as smoke, vegetation can be grown, but the species must be carefully selected. Deciduous species have an advantage over conifers in that they lose their foliage annually, whereas conifers usually retain their needles for several years. Among the species that have been recommended to stand up to smoky conditions are alder, willow, birch, mountain ash, London plane, certain species of poplar and Corsican pine.

A hazard to the success of spoil mound plantations that has nothing to do with choice of species or method of planting is the possible interference with, and injury and ultimate destruction of, the trees by animals or human beings. Fencing affords protection, but is expensive and not necessarily effective where children are concerned. It is far better to give them a personal constructive interest in the plantation by enlisting their help in its establishment.

The ultimate value of tree plantations depends not only on the successful establishment of the plants but also on their subsequent care, particularly in the early stages of development. Close attention should also be given to the sequence of succession that will best meet the needs of the planning authorities and at the same time satisfy ecological requirements.

With reference to the problem of spoil-mound reclamation in Great Britain, the general conclusion that can be drawn after visiting representative areas in the Birmingham conurbation and in South Wales is that a great deal can be done in a short period, and reasonably soon after tipping has stopped, provided soil analyses are made and expert advice taken regarding the selection of species and the methods that are to be adopted. A full statement of the information available from the literature and from local experience is now in preparation, to be issued as a Joint Publication of the Imperial Agricultural Bureaux.

# OBITUARIES

## Sir Julien Cahn, Bart.

SIR JULIEN CAHN, BART., who died on September 26, aged sixty-two, was known to a wide circle as a keen sportsman; he was particularly interested in cricket and he took teams to many parts of the Empire and to many countries. He was a far-seeing philanthropist, being a generous supporter of medicine and hospitals and particularly of the cause of reducing maternal mortality. It was due, too, to Sir Julien Cahn's munificence that it was possible to found the Cahn Hill Improvement Scheme in connexion with the University of Wales, Aberystwyth—that was in 1932 and before any purposeful action was being taken to increase home food production in the event of war. The nation owes much to Sir Julien Cahn because, as a result of the experiments then started on the hill and rough lands of Wales, the foundations were laid for establishing a technique applicable to the radical improvement and more intensive utilization not only of such lands but also of much neglected pasture in the lowlands.

During the War of 1914–18, the rough and hill lands of England and Wales (more than 5,000,000 acres) made no materially increased contribution to our food resources: in this War the matter has been very different, as is well exemplified by the pioneer endeavours of the Montgomeryshire War Agricultural Committee and by the work undertaken by the Committees in Lancashire and Breconshire and by those of many other counties of England and Wales. The success and magnitude of all this work have been, in no small measure, due to the good and quick start that was rendered possible by the results of the investigations which Sir Julien Cahn had so largely financed. Of the many lessons of the War, few are more compelling than the emphasis that must necessarily be put on the importance of the rising generation and on a thriving agriculture, capable at all times of producing an abundance of food.

The War has, therefore, greatly accentuated the wisdom behind, and the value to the nation of, Sir Julien Cahn's benefactions—benefactions which have served as an inspiration to large numbers of workers in two of the most important fields of national endeavour.

R. G. STAPLEDON.

## Prof. F. Plzák

NEWS has reached London that the death of Dr. F. Plzák, professor of organic chemistry at the Charles University of Prague, occurred there on May 4. Prof. Plzák, who was sixty-six years of age, had occupied the chair of organic chemistry since 1910 and was at one time well known in America and to a less extent in Great Britain, being a frequent visitor prior to the outbreak of the War of 1914–18. Before entering the University he was employed in a pharmacy and did not graduate until he was twenty-five years old. Then he went to Zurich to study under Prof. Lorenz before becoming, first lecturer and then (1910) professor of organic chemistry. His researches were not numerous and mainly related to the lesser known alkaloids (for example, tubocurare) and glycosides (for example, cyclamin, $C_{63}H_{110}O_{32}$, which he found in potatoes as well as in cyclamen tubers, and showed to contain various sugar groups). Plzák was part-author (with Prof. Baborovský) of a standard Czech work on electrochemistry.

As a part of the Czech University, his laboratory was closed by the Germans in 1939 and Plzák, like the other professors, was relieved of his post. Afterwards the Chemical Institute was reopened with a German staff.

WE regret to announce the following deaths:

Dr. E. L. G. Clegg, director of the Geological Survey of India, on September 8.

The Right Hon. Sir William Mulock, K.C.M.G., vice-chancellor (1881–1900) and chancellor since 1924 of the University of Toronto, on October 1, aged one hundred.

# NEWS and VIEWS

## University of Ankara

THE University of Ankara has appointed the following, nominated by the British Council, to professorships: Mr. B. E. C. Davis, reader in English language and literature, Westfield College, University of London, to the chair of English; Dr. W. J. McCallien, Carnegie teaching fellow in geology in the University of Glasgow, to the chair of geology; and Prof. J. A. Strang, professor of mathematics in the University of Lucknow, to the chair of mathematics.

British scholars already occupy ten chairs at the University of Istanbul, as follows: Prof. C. E. Bazell (English philology); Prof. F. H. Constable (physical chemistry); Prof. P. du Val (mathematics); Prof. V. H. Legg (industrial chemistry); Prof. A. K. McIlwraith (English); Prof. W. C. W. Nixon (gynæcology); Prof. J. S. Rankin (theoretical mechanics); Prof. F. Royds (astronomy); Prof. the Hon. Stephen Runciman (Byzantine art); Prof. Ronald Syme (ancient history).

## British Trade Associations: Structure and Functions

THE broadsheet "British Trade Associations" which has been issued by P E P gives a description of the structure and activities of these associations, which should provide a useful factual basis for discussion of a subject much to the fore at the present time. The arguments for and against trade associations and related questions of policy are not considered, but this well-documented summary of the internal structure, functions and techniques of trade associations and of recent trends, such as the growth in numbers, in the representation both of firms and of output in a given trade, the range of activities, the growth of distributive and composite associations, and the coalescence of trade associations, should at least stimulate the growth of informed opinion of this subject and facilitate its objective discussion. In regard to technical functions, trade associations have furthered co-operation in such matters as standardization, pooling and interchange of patents, and research. Discussion and negotiations with Government departments and co-operative advertising are also considerable spheres of activity. Commercial functions may be distinguished as non-regulative, such as credit bureaux, mutual insurance schemes, market research, and, less frequently, joint purchase of materials and regulative activities. The latter are of four types: control of prices, as by price agreements; control of the channels of distribution; the regulation of productive activity; and the centralization of selling activities. Examples illustrating all these activities are cited in the broadsheet, which also points out that in practice it is not always easy to maintain the distinction between trade associations concerned primarily with trade, and employers' federations which are concerned primarily with labour questions.

## Royal College of Physicians of Edinburgh

ALTHOUGH research work is the major occupation of the staff of the Laboratory of the Royal College of Physicians of Edinburgh, the Laboratory has, during the War, been occupied with Government work for the Armed Forces and for the Emergency Medical Services. In the annual report for 1943 of the Curator, it is stated that the agreement between the College and the Carnegie Trustees for the Universities of Scotland, made forty years ago, is being modified as from this autumn. The Trustees will retain the proprietor's obligations in respect of the building in which the Laboratory is situated and will contribute £1,000 a year for research for five years, but the treasurer of the Carnegie Trust will no longer do the Laboratory's accounting work. The retirement of Mr. James Davidson, who for forty years has acted as the Laboratory's treasurer and financial adviser, ends a long and devoted service. Plans for reorganization and future work depend on the development of post-war medical schemes in general.

Considerable work has been done by the Laboratory on the histology of cancer, on sarcoma of the breast and on tumours of the adrenal gland, the nervous system and the pituitary gland. Other problems studied have been congenital microphthalmos in mice, a research promoted by the Ross Foundation for the Study of Blindness, Edinburgh; the diagnosis of sterility; and the study of hæmoglobin and the testing of hæmoglobinometers. The Biochemistry Department, directed by Dr. W. O. Kermack, who also directs the Department of Statistics, has continued the difficult study of the synthesis of new anti-malarial drugs, and considerable progress has been made. The Bacteriological Department has studied the anaphylactic theory of rheumatic diseases and is engaged on the typing of pneumococci and on chemotherapeutical research on corneal infections, which has shown that the cornea of the rabbit is highly susceptible to the gonococcus and can be used for chematherapeutic research on this organism. Work on blood groups is planned for the future. During 1943 the Laboratory issued 22,461 reports on laboratory findings, and this side of its work is increasing. This work provided a revenue of £5,744, with a profit of £781; it is thus a valuable help to the finance of a laboratory which is not run for profit, but seeks only to maintain itself and to contribute to the advancement of knowledge.

## Paper for School Text-books

IN reply to a question in the House of Commons on October 12 referring to the shortage of school text-books, Mr. Butler, Minister of Education, said: "I have been in touch for some time with those of my colleagues who are concerned with the object of securing an increase in the allocation of paper for educational books, and I am glad to say that, in spite of the many pressing calls upon the available supplies, a substantial additional tonnage of paper has now been allocated which should go a considerable way towards meeting the most urgent cases of shortage."

## The Reversible Transit Circle, Greenwich

Sir Harold Spencer Jones and R. T. Cullen (*Mon. Not. Roy. Astro. Soc.*, **104**, 3; 1944) describe the principal features of, and preliminary results of tests and observations with, the new reversible transit circle of the Royal Observatory, Greenwich. The instrument was installed in 1936 and replaced the transit circle designed by Airy and installed in 1851. This latter instrument had a wonderful record for work, and the value of the Greenwich meridian observations is due very largely to the continuity of observation with the Airy transit circle. The new instrument was constructed by Messrs. Cooke, Troughton and Simms, Ltd., and follows closely in design the reversible transit circle of the Cape Observatory, designed by Gill. After the erection of

the instrument in February and March 1936, various kinds of researches were initiated, concurrently with observations for the establishment of a fundamental system of right ascensions. The work was interrupted in the autumn of 1940 owing to air attacks on London, and the objectives of the instrument and the two collimators and the micrometer eye-end were dismounted and removed to a place of safety. Fortunately sufficient material had been obtained and conclusions formed to guide the planning of post-war observations with the instrument.

The investigations have shown various ways in which systematic discordances of instrumental origin can enter into meridian observations, and the results may be useful to others who are planning a similar equipment. The paper gives the results of the investigation of the diurnal and seasonal changes of the instrumental errors of adjustment, and it is pointed out that a close control over the error of collimation will be essential when the instrument is brought into use again. A pronounced effect of wind directions on azimuth error has been shown to exist, the correction being a maximum, 0·33″, when the direction of the wind is north.

## Spot Gluing by High-Frequency Heating

ONE of the advantages of high-frequency heating as applied to dielectrics is that it is very easily localized by the use of two small electrodes placed close together. Heating is confined to the material in the relatively strong electric field in the immediate neighbourhood of the gap between the electrodes. A pair of electrodes mounted in a suitable handle and connected by a flexible coaxial cable is sometimes used rather like a soldering iron for the gluing of joints in wood structures. Synthetic resin glues can be heated to the setting point in a few seconds. Another arrangement of electrodes in the form of two small wheels which roll over the opposite faces of sheets of material passing between them has been used as an 'electric sewing machine' for cementing together sheets of material.

Yet another device of this kind is a 'spot gluing' outfit recently developed by Pye Telecommunications, Ltd., in co-operation with Aero Research, Ltd. The electrodes are mounted in the form of a gun, the active electric field occupying the space between the end of the gun barrel and a central electrode coaxial with it. The central electrode is spring-mounted and projects slightly beyond the barrel, and pressure of the electrode on the work is made to operate switches, so that the power is automatically applied for an appropriate time interval, say, 2 sec. In operation, therefore, the process is closely analogous to spot welding, although it is used for tacking components into position when building up a complicated assembly, rather than for making complete joints. The importance of the process lies mainly in the fact that it holds out the possibility of dispensing with the use of brads, metal staples, clamps, etc., in forming some of the complex structures required in aircraft work.

## Crop Rotation

AN entirely new and re-written edition of Bulletin No. 85, "Rotations", has been published by the Ministry of Agriculture and Fisheries (H.M. Stationery Office, *4d.*). The author is Dr. H. G. Sanders of the School of Agriculture, Cambridge, as Prof. R. G. Whyte, writer of the previous editions, was unable to undertake the necessary revision. The principles of rotations are set out clearly, and the Norfolk four-course rotation, which had been followed for some two hundred years on the lighter soils of England, is discussed in some detail. During the last thirty years, however, this system has had to be radically altered to meet changed economic conditions, and cash crops of high value, such as sugar beet and potatoes, have been introduced. The extension of the rotation by means of the seeds ley is discussed, and a separate section is devoted to the special problems on heavy land, while catch-cropping forms the subject of the final section of the bulletin. Emphasis is laid on the fact that for successful farming a thorough understanding of traditional methods is the only sound basis for deviation from established practice.

## Chemotherapy and Tropical Medicine

IN a lecture to the Chemical Society (*J. Chem. Soc.*, 351; 1943), Dr. A. J. Ewins dealt with the above subject, and his lecture is particularly interesting in giving a concise historical account of the development of the use of chemical agents in the treatment of tropical diseases, which are caused not only by bacteria but also by virus, protozoal and parasitic infections. One of the first applications was in the treatment of sleeping sickness, in which the work of Ehrlich was predominant; for many years this field of investigation was one of the major concerns of the great German firms dealing with synthetic drugs, and these may be regarded as having taken a most prominent role in the welfare of parts of the world which otherwise looked to Great Britain as the proper source of research into matters so intimately affecting the Empire. Dr. Ewins is able to show, however, that a start has been made in overtaking the great gap between the development of research in chemotherapy in Britain and our responsibilities to the British Empire, and that the potentialities of such research are now being realized. The lecture is very concise and readable, and is recommended to the attention of all who may be concerned with Empire matters.

## U.S. National Vitamin Association

THE organization in the United States of a National Vitamin Foundation was approved at a meeting of fifty representatives of all sections of the vitamin industry in New York on May 23 (*J. Amer. Med. Assoc.*, July 28). Its objects are to award grants for research in the vitamins or related fields, the dissemination of information in the vitamin trade, medical profession and public with respect to the quality, purposes and uses of vitamins, and to confer and consult with medical societies, medical schools, health organizations, public health agencies and government agencies with respect to vitamins and the vitamin industry. The Foundation will be administered by a board of trustees. Details of the organization are to be formulated by a committee of which Basil O'Connor, New York, president of the National Foundation for Infantile Paralysis, has been made chairman.

## Recent Earthquakes

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of three recent earthquakes. The first was on June 28 at 7h. 58·9m. G.M.T. with an epicentre at latitude 14·6° N., longitude 92·6° W., off southern

Mexico. This shock was registered at fifteen American stations and at Honolulu, Ottawa and Toledo (Spain), but not in any strength at Wellington, New Zealand. The second shock was on July 12 at 19h. 30·4m. G.M.T. from an epicentre at latitude 44·7° N., longitude 114·4° W. in Idaho. This was recorded at six United States seismograph stations. The third shock was on July 19 at 10h. 20·9m. G.M.T. from an epicentre at latitude 33° N., longitude 138° E. (off Japan). This was recorded at five U.S. stations and at Honolulu. All interpretations and calculations are tentative. During June twenty-two local earthquakes were felt in New Zealand. One, on June 28, may have attained an instrumental magnitude of 5½. This was felt in eastern and southern parts of North Island and at Nelson just after 13h. 14m. G.M.T. The shock of June 26 had instrumental magnitude 5 and was felt at Gisborne, Hawkes Bay and Taupo region. Several shocks had Scale 4 intensity.

## New Division of the Institution of Civil Engineers

THE Council of the Institution of Civil Engineers has approved the formation of a fifth division to be known as the Works Construction Division, under the chairmanship of Lieut.-Colonel C. M. Norris. Its objects are: "The promotion of the science and art of engineering in relation to the ways and means of carrying out engineering construction on the site: e.g. the use of machinery and plant, the design and maintenance of temporary works, the organization of engineering labour (including foremen and inspectors), and the use and inspection of materials". The opening meeting will be on January 2, 1945, when there will be a discussion on a report on "The Organization of Civil Engineering Work", recently prepared by the Institution and to be available shortly. All corporate members of the Institution who wish to apply for registration as members of the Division should inform the Secretary by postcard, giving name (in block letters), address, and grade in the Institution. The fourth division, approved also during 1944, was the Maritime Engineering Division dealing with harbours and docks, together with works of coastal protection and the like, under the chairmanship of Mr. Asa Binns. This will hold its first meeting on February 13, 1945. The other three divisions of the Institution are those of Road Engineering, Railway Engineering and Structural and Building Engineering.

## Research Grants by the Society of Sigma Xi

ELEVEN grants-in-aid, totalling 2,415 dollars, have been made by the Society of the Sigma Xi, the national honorary research society of the United States. The committee which made the awards consisted of Dr. Harlow Shapley of Harvard College Observatory (president of the Society of the Sigma Xi), Dr. Hugh S. Taylor of Princeton University, and Dr. L. C. Dunn of Columbia University. They are as follow: Robert O. Bloomer, Corcoran School of Geology, University of Virginia, 200 dollars for aid in the study of Pre-Cambrian rocks of the Beartooth Mountain, Montana; Miles P. Givens, Pennsylvania State College, 100 dollars for aid in the investigation of the quantum nature of X-rays; C. Clayton Hoff, Department of Biology, Quincy College, 200 dollars for assistance in bibliographical work and to defray part of the expense connected with the study of the pseudoscorpions (taxonomy and distribution); Frank M. Hull, Department of Biology, University of Mississippi, 150 dollars for the continuation of the study on *Baccha* and *Mesogramma* and related genera of Syrphid flies. Yingchen Li, Department of Forestry, National Szechwan University, China, 500 dollars for the study of seed-production of several varieties of *Aleurites fordii*, the Chinese tung oil tree; David C. McClelland, Department of Psychology, Wesleyan University, 100 dollars for assistance in the preparation of a new scoring key for the Bernreuter personality inventory and for the Strong vocational interest test; Marie B. Morrow, Department of Botany and Bacteriology, University of Texas, 240 dollars for aid in the continuation of studies on methods of preparation of allergenic mould extracts; Donald M. Pace, Department of Physiology, University of Nebraska, 250 dollars for technical assistance in the continuation of studies on growth phenomena in *Chilomonas*; Hugh M. Raup, Department of Plant Ecology, Harvard University, 400 dollars for use in defraying expenses in connexion with the continuation of studies on the botany and plant geography of regions along the new Alaska Military Highway; Sidney Roberts, Department of Physiology, University of Minnesota Medical School, 150 dollars for aid in the study of the source and control of gluconeogenesis in the kidney; Pierre Van Rysselberghe, Department of Chemistry, University of Oregon, 125 dollars for aid in the study of the conductivity of non-aqueous solutions of metallic salts.

## Announcements

THE Paris correspondent of *The Times* states that Prince Louis de Broglie, Prof. Pasteur Vallery Radot and M. André Siegfried have been elected members of the Paris Academy of Sciences, and M. Georges Duhamel has been appointed *secretaire perpetuel*.

THE Lord President of the Council has appointed Sir Frank Smith to be chairman of the Road Research Board of the Department of Scientific and Industrial Research, in succession to the late Sir Clement Hindley.

THE Council of the University of Sheffield has made the following appointments: Dr. Z. P. Dienes to be temporary assistant lecturer in mathematics; Dr. I. F. S. Mackay to be lecturer in experimental physiology; and Mr. H. Lewis, Mr. J. Sedgwick, Mr. S. Waterworth and Mr. D. White to be part-time teachers in engineering.

AT the annual general meeting of the London Mathematical Society on November 16, in the rooms of the Royal Astronomical Society at 3.0 p.m., Prof. Jacques Hadamard, of the Paris Academy of Sciences, will give a lecture, "Psychological and Personal Recollections of a Mathematician". Members of other scientific societies will be welcome.

PROF. S. K. MITRA, of the University College of Science, Calcutta, and chairman of the Radio Committee of the Board of Scientific and Industrial Research of India, who is one of the delegation of Indian men of science now visiting Great Britain, will give a lecture on "Active Nitrogen" at a meeting of the Physical Society to be held at the Cavendish Laboratory, Cambridge, on October 24 at 2.30 p.m.

THE one hundred and fiftieth course of six lectures "adapted to a Juvenile Auditory", the well-known Christmas Lectures given at the Royal Institution, will be delivered by Sir Harold Spencer Jones, Astronomer-Royal, on December 28, 30, January 2, 4, 6 and 9 at 2.30 p.m.

## Persistence of D.D.T. in Oil-bound Water-Paint

THE property of D.D.T. of becoming firmly adsorbed on to a surface was demonstrated in the early work of Wiesmann[1], when he found that it was possible to render walls effective against stable-flies and house-flies for periods of about two months by spraying a suspension of a powder impregnated with 5 per cent of D.D.T. Another interesting application of this property is to be found in the fact that garments impregnated with a solution of D.D.T. withstood 6–8 weeks wearing and six to eight launderings before losing their insecticidal efficacy[2]. It has been reported[3] that beds sprayed with a kerosene solution containing 10 per cent of D.D.T. and 5 per cent of cyclohexanone retained the power of killing bedbugs for 104 days after treatment.

The outstanding persistence effect of D.D.T. raises the question as to whether it might be incorporated in paint or other surface coatings, and during the past year we have been investigating this application with promising results[4].

It is natural to expect that if the D.D.T. powder is but lightly bound to the surface, as say, in whitewash or dry distemper, there is every prospect of retaining the insecticidal action; but on the other hand, in the more durable coatings such as oil paints and synthetic varnish paints, one might expect the D.D.T. particles to be prevented from exercising their insecticidal effect because of the strongly adsorbed oil film. These expectations were, in fact, confirmed by our results; but we were particularly pleased to find that when D.D.T. is incorporated in an oil-bound water-paint it continues to exert its insecticidal action.

In the laboratory experiments, plywood was cut to fit inside zinc mesh fly cages. The first cage had plywood—painted with D.D.T. (5 per cent) paint—covering the floor, half-way up the sides and two thirds of the lid, whereas the second cage was covered with an identical area of plywood painted with the same paint in which D.D.T. had not been incorporated. One hundred housefly pupæ in a crystallizing dish were placed in each cage together with containers of sugar and water, and the cages were inspected daily.

The results of one typical experiment are summarized below:

| Date | Cage fitted with wood painted with oil-bound water-paint and D.D.T. | | Cage fitted with wood painted with oil-bound water paint as control | |
|---|---|---|---|---|
| | Flies alive | Flies dead | Flies alive | Flies dead |
| 22/3/44 | 6 | 1 on its back waving its legs | 4 | Nil |
| 23/3/44 | 4 | 3 | 20 | Nil |
| 24/3/44 | 5 | 6 | 35 | Nil |
| 25/3/44 | 6 | 10 | 35 | Nil |
| 27/3/44 | 1 | 15 | 86 | Nil |
| 28/3/44 | Nil | 68 | 86 | Nil |
| 29/3/44 | Nil | 90 | 86 | Nil |
| 30/3/44 | Nil | 93 | 86 | Nil |

From these results it will be seen that the oil-bound water-paint incorporated with D.D.T. was effective against houseflies, and tests carried out after two months showed that the paint had not lost its insecticidal properties.

Small rooms were then painted with a D.D.T. paint, and by a fortuitous mistake the oil-bound water-paint used contained only 0·5 per cent of D.D.T.—exactly one tenth the amount used in the laboratory experiments. It was then found that 90 per cent kills of houseflies were obtained overnight as compared with negligible kills in an identical room painted with the oil-bound water-paint containing no D.D.T. It has proved difficult to obtain accurate and reproducible data for the distribution of the flies on the various surfaces of the room, but our preliminary observations indicate that the flies tended to avoid contact with the D.D.T.-painted surface. Our experiments continue with oil and resin media, and there is already evidence that in certain continuous film-forming media D.D.T. retains its insecticidal effect.

The results now being obtained in a factory canteen painted with this D.D.T. oil-bound water-paint are fully supporting the results obtained in the laboratory and laboratory-field experiments. The social implications of these findings need no stressing.

A full account of this work will be published elsewhere.

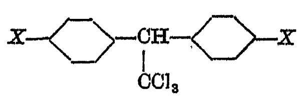
## Insecticidal Action of D.D.T.

A STUDY of the insecticidal properties of D.D.T. (αα-bis (4-chlorphenyl)-βββ trichlorethane; I, $X$=Cl) and its analogues, carried out in this laboratory,



(I)

has led to a working hypothesis on their mode of action which has enabled the prediction of insecticidal activity in related compounds.

Although D.D.T. is chemically unreactive and stable to long boiling with water, it readily loses hydrochloric acid to alcoholic alkali or on heating to form αα-bis(4-chlorphenyl)-ββ-dichlorethylene. This compound as well as 4 : 4′-dichlorbenzophenone and bis(4-chlorphenyl) acetic acid are almost inactive both as contact and stomach insecticides, indicating that the $>CH-CCl_3$ group is associated with insecticidal activity.

It is possible that the toxicity of D.D.T. is due to its chemisorption at vital centres, with interference with essential enzyme systems. In view of its chemical inertness, however—for example, no evidence of compound formation between D.D.T. and either the 'acceptor' phenolic hydrogen of the naphthols or the 'donor' nitrogen of the naphthylamines was obtained from melting-point curves—the alternative hypothesis of the intracellular decomposition of D.D.T. is preferred. As the ethylene derivative is non-toxic although presumably sharing the permeativity

of D.D.T., the toxicity of the latter is ascribed to the hydrochloric acid simultaneously produced either by elimination or reduction.

The insecticidal activity of a compound to which this hypothesis is applicable would then depend on the ease with which hydrochloric acid is produced, provided that the compound is stable enough to survive translocation to its site of action. Preliminary work has shown that some other compounds, for example, certain chlorinated cyclic polymethylenes and non-aromatic substituted ethanes susceptible to this decomposition are insecticidal, whereas related compounds from which hydrochloric acid elimination is not possible are inactive.

On the other hand, diphenyl trichlorethane (I, $X = H$) loses hydrochloric acid readily to alkali yet is relatively non-insecticidal. An additional factor, lipoid solubility of the molecule as a whole, is therefore operative. The chlorphenyl groups of D.D.T. would be expected to confer high lipoid solubility and thus high permeativity. The more polar dihydroxy derivative (I, $X = OH$) and its diacetate, with lower lipoid solubilities, are less insecticidal than the dimethyoxy-analogue of D.D.T. (I, $X = OMe$).

Fuller details of this work will be published elsewhere.

## Experimental Corroboration of the Mechanism of Biological Action of Quinones of the Type of Vitamin K

A HYPOTHESIS was suggested[1,3] in the course of chemical and biochemical studies of the anti-hæmorrhagic compounds that the activity of the quinones of the vitamin K group is due to their bio-oxidative decomposition to phthalic acid and is largely a function of their capacity for transformation into this acid. It is phthalic acid that is apparently to be regarded as the carrier of the biological properties of such quinones.

These statements were based on the following experimental evidence. (1) The quinones of the type of vitamin K are extremely liable to transformation into phthalic acid merely when warmed with water[2]. (2) The structural peculiarities of quinones that give them anti-hæmorrhagic activity are also responsible for their capacity for transformation into phthalic acid[3]. (3) The transformation of such quinones into phthalic acid is linked with the capacity of their molecules for tautomeric transition to a peculiar alycyclical system which is easily oxidizable into phthalic acid[1,2,3]. (4) It was found, on the other hand, that phthalic acid itself possesses a weak[4], and some of its derivatives, for example, diethylphthalate[3], a significant, anti-hæmorrhagic activity. The smaller activity of phthalic acid as compared with diethylphthalate as well as with quinones of the vitamin K type is presumably due to the rapid excretion of this acid from the organism (for details cf. ref. 3). (5) The quinones of the vitamin K type undergo very rapid changes in the blood (cf. J. V. Scudi and R. P. Buchs[5]), although their anti-hæmorrhagic action is known to appear only after a considerable lapse of time. This likewise suggests that these quinones apparently do not circulate within the organism as such at the moment when the anti-hæmorrhagic action becomes manifest, and that the effect at issue is elicited not by these substances but by the products of their transformation.

It occurred to us that one of the most conclusive pieces of evidence supporting the above suggestions as to the mechanism of biological action of the quinones of the vitamin K type would be their transformation within the organism into phthalic acid. It seemed, therefore, worth while to study the metabolism of both phthalic acid and of 2-methyl-1,4-naphthoquinone (the so-called vitamin $K_3$) in the dog and man.

Upon repeated subcutaneous administration to dogs (weighing 12–13 kgm.) of appreciable doses of a rather concentrated aqueous solution of a bisulphite derivative of 2-methyl-1,4-naphthoquinone (total dose about 0·8 gm.) phthalic acid was isolated from the urine and afterwards identified as phthalic anhydride. Urine was shown to lack both 2-methyl-1,4-naphthoquinone and its bisulphite derivative as well as 2-methyl-3-oxy-1,4-naphthoquinone (phthiocol). Phthalic acid was also found in human urine upon subcutaneous injection of 50 mgm. bisulphite derivative of 2-methyl-1,4-naphthoquinone dissolved in water. Nevertheless, phthalic acid itself as well as its di-sodium salt are practically completely excreted after subcutaneous injection of an aqueous solution both in man and the dog without undergoing any changes. This was shown by J. Pohl[6] in the dog and by us in man. The urine of a control man or dog does not contain phthalic acid at all. Hence it follows that phthalic acid is the metabolic end product of 2-methyl-1,4-naphthoquinone.

Thus, our previous hypothesis as of the mechanism of biological action of quinones of the vitamin K group is substantiated not only by the anti-hæmorrhagic activity of phthalic acid but also by the capacity of such quinones for transformation into phthalic acid both *in vitro* and *in vivo*.

Mention must also be made of the publication by K. P. Link *et al.*[7] on the mechanism of the hæmorrhagic action of 3,3′-methylene-4,4′-dioxydicumarin, which is an antagonist of vitamin K. It was shown by these authors that salicylic acid possesses the same type of biological action as 3,3′-methylene-4,4′-dioxydicumarin. As the former is apparently the metabolic product of the latter, it may be regarded as the carrier of its hæmorrhagic functions.

These data become particularly interesting if we recall that, according to our finding, phthalic acid is not only the metabolic end-product of quinones of the vitamin K type, but obviously also the carrier of their anti-hæmorrhagic function.

## Specialized Analgesic Effects of β-Hydroxy-α : β-diphenylethylamine

CLINICAL trials by other workers not yet reported have confirmed our original observation[1] that β-hydroxy-α : β-diphenylethylamine will relieve pain due to pressure on nerve in patients with inoperable tumours. This was the only type of pain included in our trials, and it is now clear that the compound has no universal analgesic action and cannot be used generally as a substitute for morphine. Tests using the method of Sivadjian[2], which measures the tolerance of rats to electric shocks, have now been carried out with morphine and the diphenylethylamine compounds the morphine-like properties of which we have described[1]. The results, which will be reported in detail elsewhere, were entirely negative for the diphenylethylamine compounds; but analgesic activity was demonstrated in the hydrochlorides of morphine and pethidine, showing that the negative results were not due to the method used. The cause of the specific action of β-hydroxy-α : β-diphenylethylamine on nerve pressure pain awaits further pharmacological investigation.

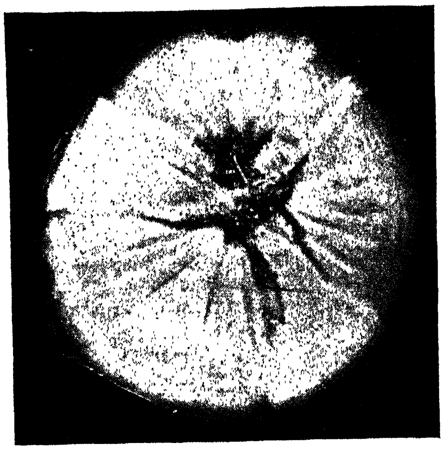
## Genetic Proof of Heterokaryosis in *Penicillium notatum*

IN a recent paper, Baker[1] has given an account of nuclear behaviour in *Penicillium notatum*. We had, independently, reached the same conclusions, summarized as follows: (*a*) the older 'cells' of the mycelium, the sterigmata and the conidia are usually uninucleate; (*b*) the 'cells' at the growing edge of the colony are usually multinucleate, containing up to a dozen nuclei each; (*c*) hyphal fusions occur between branches of the same hypha and also between hyphæ of different origin. From her cytological work, Baker infers that *P. notatum* is liable to be 'heterokaryotic', that is, may carry genetically unlike nuclei in a multinucleate cell, or in different cells of a hypha. This condition, widespread in fungi, well deserves careful investigation in view of its important implications for the theories of gene action and of the evolution of genetic systems. Some of these implications have been discussed by Hansen[2], Dodge[3], Lindegren[4] and, especially, by Beadle and Coonradt[5].

The above cytological inference, in the case of *P. notatum*, needs the support of a genetic counterproof: this can now be supplied. Even though *P. notatum* has no known sexual stage involving alternation of karyogamy and meiosis, the fortunate circumstance that conidia are uninucleate makes a genetic analysis possible. The technique—an obvious simplification of those used[3,5] for species with a sexual stage and multinucleate conidia—is as follows: (1) production by X-rays of mutant strains; (2) mixed inoculation two by two of different mutant strains; (3) search for non-mutant ('wild type') patches, or



MIXED COLONY OF TWO WHITE STRAINS SHOWING GREEN HETEROKARYOTIC PATCHES AT THE CENTRE AND ALONG THE LINES OF CONTACT BETWEEN THE TWO STRAINS.

for patches differing from either strain, at the centre of the mixed colony and along the radii where the mycelia of the two strains are in contact. The following are the results of mixed inoculation two by two of five such X-ray induced mutants, all characterized by a reduced pigmentation of conidia or by complete failure to form conidia. The formation of patches with wild type (green) conidia, or with conidia differing from those of either parental strain, is represented by +, and failure to form such patches by —.

| Designation of strain | Type of conidium | Results of mixed inoculation | | | | |
|---|---|---|---|---|---|---|
| | | *y*—1 | *w*—16 | *w*—2 | *w*—3 | 2*C*4 |
| *y*—1 | yellow | — | + | + | + | — |
| *w*—16 | white | | — | +* | + | — |
| *w*—2 | white | | | — | + | — |
| *w*—3 | white | | | | — | — |
| 2*C*4 | no conidia | | | | | — |

* Very pale green conidia.

All combinations of any two of the first four strains, and none of the combinations involving the non-conidial strain 2*C*4, produce patches of mycelium with green conidia, or with conidia differing from either of the strains used (see accompanying reproduction). When these conidia are plated out, the two component strains are recovered, thus confirming that fusions between hyphæ of the two strains had taken place, followed by migration of nuclei from one strain to the other, and the nuclei segregated later. Segregation of parental nuclei does not take place at the formation of the conidiophore but at some stage between this and the formation of conidia, probably at the formation of the sterigmata. In fact, even though each conidium gives rise to one or the other parental type, both types may be recovered from different conidia of the same (green) penicillus.

Points of interest are, first, that despite the fact that each conidium carries a single nucleus, all those of one penicillus are uniform in their pigmentation: hence this pigmentation is controlled not by the genetic constitution of the nucleus segregated into each conidium, but by the constitution of the hypha from which the penicillus arose. Secondly, if the familiar criteria of genetics are valid in the present case, four out of the five X-ray mutations tested, namely, *y*-1; *w*-16; *w*-2; *w*-3, behave as if they were recessive, involving four different loci. As for the fifth mutation—the non-conidial 2*C*4—failure to produce green conidia in mixed inoculi is probably due to dominance of the non-conidial effect, as inter-

strain hyphal fusions have been seen to occur also with this strain. Should this inference be confirmed, the high frequency with which non-conidial mutants have been found, even without irradiation[6], would simply be the consequence of dominance.

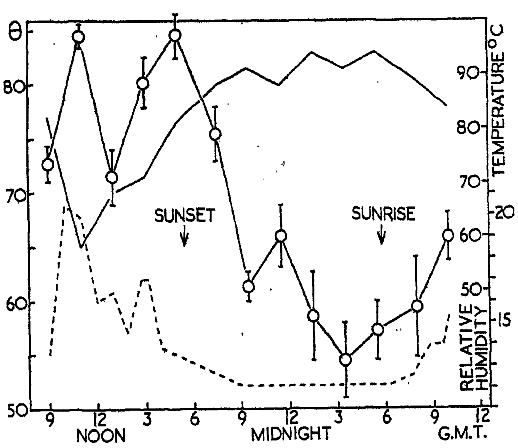
## Diurnal Fluctuation in a Physical Property of Leaf Cuticle

The extent to which the outer surface of a leaf is wetted by water may depend on factors varying with species, age, and position on the plant. A series of investigations on advancing contact angles has made it clear that, in addition, the adhesion of water for leaf surfaces may vary considerably with the condition of the leaf, and, in particular, with factors showing a cyclic diurnal change.

Measurements made at intervals over periods of up to 26 hours have shown the existence of distinct diurnal fluctuations in the magnitude of the advancing contact angle of water on the leaves of the two plant species so far investigated from this point of view. Contact angles were determined by a method similar to that of Ebeling[1], in which a value is derived from the characteristics of the curve obtained by tracing the projected profile of a drop resting on a horizontal surface. The accompanying graph represents results obtained with *Brassica sinapis* Visiani growing in an outdoor plot. Contact angle increased after dawn, reaching a maximum in the afternoon and falling after sunset to a minimum before sunrise. The difference between the two extremes was of the order of 30°. In other experiments contact angle has been observed to rise again to a second maximum after the minimum occurring about four hours after sunset, afterwards falling once more to a low value



Diurnal fluctuation in the advancing contact angle of water (θ) on the upper surface of leaves of *Brassica sinapis* Visiani growing in an outdoor plot (September 1943). Each value is the mean of ten determinations, the standard deviation of the mean being indicated. Contact angle, ——O——; relative humidity (by whirling hygrometer), ———; temperature, - - - - -.

just after dawn. Essentially similar fluctuations through a smaller range (6–9°) have been found to occur in *Triticum vulgare* Host. under both greenhouse and outdoor conditions. When the two species have been compared, the changes in contact angle of *Triticum* have been found to parallel very closely those of *Brassica*.

In detached leaves the effect of temperature has been found to be negligible; but a marked rise in the value of contact angle has been observed in wilting leaves and it appears that the water relations of the leaf are of considerable importance in determining its magnitude. The following results were obtained using the upper surface of leaves, removed in the morning from young *Triticum* plants, left to dry out under laboratory conditions of temperature and humidity. Control leaves, kept from the start of the experiment with their cut ends immersed in water, showed no statistically significant change in the characteristics investigated. Each value for contact angle is the mean of nine determinations.

| Time in hours | 0·0 | 0·5 | 1·0 | 1·5 | 2·0 | 2·5 | 4·0 |
|---|---|---|---|---|---|---|---|
| Mean contact angle for water (θ) | 123·7° | 128·6° | 133·2° | 138·3° | 141·6° | 145·2° | 152·4° |
| Standard deviation of θ | 2·0 | 2·2 | 1·9 | 1·1 | 1·7 | 0·8 | 2·7 |
| Wt. of leaves as % of initial value | 100·0 | 96·0 | 92·1 | 86·2 | 84·5 | 82·4 | 72·0 |

Such a change in contact angle is fully reversible on recovery of turgor. Thus the contact angle of water on *Triticum* leaves rose on wilting for three hours from 117·7° ± 2·3 to 146·0° ± 0·8, but returned to 118·4° ± 2·4 after the leaves had stood with their cut ends in water for a further three hours. Water applied directly to the surface of the leaf appears to be ineffective in restoring the low value of contact angle.

The contact angle of water on wilted or turgid leaves stretched uniformly has been found not to differ appreciably from that on similar unstretched leaves. It seems unlikely, therefore, that the observed changes in the surface properties of the cuticle can be due simply to alteration in the closeness of packing of hydrophilic or hydrophobic units, produced by expansion or contraction in response to turgor changes. Variation in the extent of water-imbibition of the cuticle is possibly of more importance in determining the magnitude of contact angle.

## Wilting of Shoots in Scented Geranium (*Pelargonium odoratissimum*)

*Pelargonium odoratissimum* Ait. (scented geranium) is a perennial trailing herb extensively cultivated for the essential oil present in the leaves, which is used as a cheap substitute for the attar of roses. Large numbers of these plants growing in Bangalore were parasitized by a species of *Sphæropsis* which caused the wilting of the shoots. When the infection extended up to the collar region it resulted in the death of the entire plant.

A detailed microscopic and cultural study of the fungus was undertaken and the pathogenicity of the

infecting organism was established. The pycnidia on the shoots are numerous, appearing as black specks on the surface of the shoot. The mycelium is purplish-black, intercellular and causing the death of the host cells. The size of the pycnidium is variable, and sometimes on account of coalescence they appear locular in sections. The spores are glassy, hyaline, ovate to cylindric, and measure 18–24 × 11–14 µ. In moist weather the spores emerge out of the long narrow ostiole (Fig. 1) and become brown after they are extruded from the pycnidium. Later on they become '*Diplodia*'-like, the exospore being traversed by longitudinal hyaline streaks (Fig. 2). The spores readily germinate and cause further infection of the host.

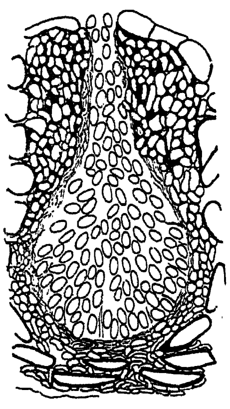

Fig. 1.

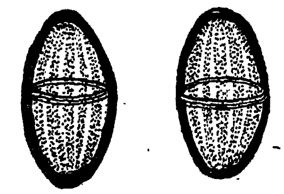

Fig. 2.

The time of colouring of the pycnospores is shown by Stevens[1] to be an important diagnostic character. He further points out the folly of attempting to decide matters relating to the life-history of this group of fungi on the basis of the association of the host[2]. Since most of the fungi belonging to this group are present on more than one host their identity becomes a matter of extreme difficulty. Recently Da Camara, De Oliveira and Da Luz[3] have recorded *Sphæropsis Pelargonii* as a new species on the shoots of *Pelargonium zonale*. Since the type of the species was not available for comparison, it was not possible to decide the identity of the *Sphæropsis* species under investigation.

I wish to express my grateful thanks to Dr. B. B. Mundkur, for help with the literature, and to Dr. L. N. Rao, for kind encouragement.

## Influence of Ultra-Violet Radiations on the Etching of Quartz

EXPERIMENTS have been carried out to investigate the influence of ultra-violet radiations on the etching of quartz by hydrofluoric acid. The quartz plate under investigation is subjected simultaneously to the actions of the corrosive acid and the ultra-violet radiations. The etching cell used consists of a short pitch-coated glass tube of which the quartz plate under study forms the bottom. The inner surface of the plate is in contact with the acid while the rim of its polished outer surface is covered by a paper ring. In this way, the ultra-violet radiations which penetrate the plate from underneath will irradiate only the central portion of its inner surface. With such a device, the two parts of an etched surface, one subjected to, and the other protected from, the action of ultra-violet radiations, can be conveniently compared. The strong ultra-violet radiations used come from a 'condensed' discharge between two iron electrodes. They are focused on the base of the etching cell by means of a quartz lens. Plates cut in different orientations and plates of amorphous fused silica have been investigated. With a moderately strong acid, the duration of each experiment lasts generally about eight hours.

(1) *Plate normal to the optic axis.* For plates of this orientation, there is a marked difference in many respects between the two portions etched. Irrespective of the original surface condition, that is, whether it is polished or unpolished, the irradiated part becomes practically transparent shortly after the introduction of hydrofluoric acid into the etching cell, while the other part becomes completely mat as usual. On examining the etched surface under a microscope, it is observed that the characteristic etching figures, namely, the well-known projecting triangular pyramids, are present in both etched portions, but with different aspect; those produced in the irradiated portion are notably flattened and changed in orientation. The transparency of this portion is undoubtedly due to the flattening of the etching figures. The sense of change of orientation of the deformed pyramids depends upon the nature of the crystal. Relative to the orientation of the normal pyramids, it is anti-clockwise for right-handed quartz, but clockwise for left-handed quartz. The angle of change of orientation increases with the intensity of the source, and an angle so large as 15° has actually been observed. In this connexion, it should be pointed out that the dissolution of quartz in the corrosive acid is far greater in the irradiated portion; this can be easily verified by comparing the depression of the surface-levels of the two etched portions. All the phenomena mentioned above will disappear if a glass plate, even as thin as 0·5 mm. in thickness, is interposed between the light source and the etching cell. A spectroscopic examination shows that the glass plate absorbs all radiations of wave-lengths shorter than some 2800 A. Hence it is clear that the observed effects on etching are due to the short wave-length radiations lying beyond this limit of absorption.

(2) *Plates of other orientations and of fused silica.* Under similar experimental conditions, the micrographic structures of the irradiated and the non-irradiated etched portions of an $X$-cut or $Y$-cut plate are almost the same, the two portions being barely distinguishable in a reflecting light. As to the fused silica plate, it is impossible to make a distinction either microscopically or macroscopically between the two etched portions in question.

The close relation between the axes of quartz and the orientation of the triangular etching pyramids has long been recognized. Recently, A. de Gramont[1] has found that the angle formed by the three faces of a pyramid of corrosion with the plane normal to the optic axis is about 29°. It was pointed out by J. B. Eck and J. Menabrea[2] that the tangent of this angle is nearly equal to the ratio $c/2a$, where $c = 5{\cdot}38 \times 10^{-8}$ cm., which represents the height of the hexagonal lattice, and $a = 4{\cdot}89 \times 10^{-8}$ cm. represents the distance between the axes of the adjacent spirals. Should this equality be not due to a fortuitous coincidence, the flattening and the change

of orientation of the elementary pyramids might be regarded as evidence of some modification of the crystalline structure by the action of the ultra-violet radiations.

## A Solar Halo Phenomenon

SIMILAR phenomena to those described by G. H. Archenhold[1] were observed in France during the War of 1914–18 near the fighting zone, and there are records of similar waves observed during this War[2]. Some of the records are, however, scattered in publications not accessible to me at the present time.

A probable explanation of this phenomenon is that it is caused by acoustic waves from explosions passing through a cloud of ice crystals. The explosions might be so distant that they may not necessarily be heard at the point of observation. The perfect straightness of the bands observed by Archenhold supports this view of their distant origin. The observed very high velocity of about 5° per second agrees well with the velocity of sound at the height at which ice clouds are forming. The spacing of the bands of ½–1°, when compared with their speed, corresponds to the frequency of 2·5–5 cycles per second, which also corresponds to the fundamental frequency of sound caused by heavy explosions.

Ice crystals floating in air are usually oriented with their greatest cross-section perpendicular to the direction of the field of gravitation, that is, platelets have their six-fold axis of symmetry vertical, needles have it horizontal. The mock sun ring is usually produced by the reflexion of light on the vertical side faces of the plates, but it might be produced sometimes by the vertical end faces of the needles. The passage of the sound waves through the cloud would produce a movement of the air relative to the crystals, due to their inertia. This would have also an orienting influence on the floating crystals, which should tend to orientate themselves with their greatest cross-sections perpendicular to the direction of the sound. The presence of the sound waves will thus disturb the vertical orientation of the crystals, and dark bands would appear in the reflexion halo approximately in the zones of maximum acceleration of the sound waves, that is, there will be two fringes for each wave-length.

The disturbances could not be explained as due to the discontinuity of the wind speed at the surface of contact of two different air masses, as such disturbances usually travel at considerably lower speeds than the speed observed by Archenhold.

It would be of great value if any additional information could be procured concerning the height of the aeroplane cloud trails formed during August 9 (not necessarily at Cambridge), and concerning any heavy explosions heard south of Cambridge.

[2] *Flight*, Aug. 8, 1940. *Times*, Aug. 31, 1944.

THE phenomenon of moving dark bands travelling across a solar halo, as reported by Mr. G. H. Archenhold[1], seems to be linked with the optical effect of blast such as results from the explosion of bombs, etc.

An account of moving dark bands passing across cirrus cloud was given by a special correspondent of *The Times* in the issue of August 31, the date of the occurrence being August 9, and the locality of the observance of the occurrence as southern England.

It would be interesting to know from Mr. Archenhold whether any gunfire was heard on the morning in question.

The optical effects of blast from flying bombs have been reported by other observers and myself within recent weeks and have appeared in the columns of *Engineering*, *The Aeroplane* and *The Times*.

In my own experience, the moving dark bands have been observed on very low stratus cloud.

## Abnormal Paranthelia

TWICE within the last year I have observed a paranthelion bearing about 165° from the sun—a position in which the paranthelion does not seem hitherto to have been reported.

The features common to the two appearances were as follows. The sky in the neighbourhood of the phenomenon was a dilute blue with wisps of cirrus. A region of the sky, covering about 3° of altitude and 5° of azimuth, was singled out by the fact that whenever a wisp of cirrus drifted into it the cloud became brilliantly luminous, without colour, and remained so until it left the region; blue sky within the region was not differentiated from that without. The centre of the region was, as nearly as could be estimated by eye, at the same altitude as the sun and approximately 15° eastward of the position which would have been occupied by the anthelion, had one been present. There was, however, no trace of anthelion, nor of any other paranthelion. Each appearance lasted some twenty minutes from the time of first observation.

The distinguishing details were as follows.

| | I | II |
|---|---|---|
| *G.C.T. of first observation* | 11.50; Sept. 24, 1943 | 11.10; Aug. 9, 1944. |
| *Place* | Moulsford Down (51° 32′ N., 1° 11′ W.) | Reading (51° 26′ N., 0° 57′ W.). |
| *Sun's altitude (computed)* | 38½° | 53½°. |
| *Bearing of centre of luminous region* | 160–165° E. of sun. | 165–170° E. of sun. |
| *Weather* | Brilliant sunshine; no cloud beyond that described below; sky-blue very little diluted; wind S.W., force 2 at ground; some cumulus blew up shortly afterwards. | Bright sunshine; much cirrus; lower cloud types in other parts of sky; sky-blue much diluted; wind N.W., force 1 at ground. |
| *Other contemporary meteoroptical phenomena* | None. | Traces of parhelic circle between 100° and 160° E. of sun. |

On occasion I no other meteoroptical phenomena were seen on the same day. On occasion II, Mr. R. Adcock and Mr. M. Barker, who directed my attention to II, reported having seen a parhelion (III) (? colourless), 46° E. of sun, at 9.15 G.C.T. on the same day. Unfortunately, no instruments were available for any of these observations, so that the azimuths are rather uncertain; III was carefully aligned on marks which were measured later.

It has been suggested that the increased frequency with which haloes and parhelic phenomena, especially of the rarer types, have been observed of recent years is due to some special tendency of condensation trails from aircraft to crystallize in the appropriate manner. Trails were being formed in other parts of the sky before and during the observation of II and III, but the clouds manifesting the paranthelion were not seen to be formed from them and had the general appearance of natural cirrus. No trails were noted on occasion I, but the clouds, which were of normal cirrus texture, had an unusual disposition. Some eight to ten dense, parallel bundles of cirrus wisps, somewhat entangled, evenly occupied a rhombus of about 20° side, outside which the sky was conspicuously cloudless.

I am unable to offer any explanation of II. I might possibly be the rare and doubtful paranthelion of 35–38°, set back by the high altitude of the sun. On the basis of Pernter and Exner's[1] tentative theory of this phenomenon, the computed bearing from the sun is 155° (observed 160–165°). Their doubts, however, have special force in this case owing to the high altitude of the sun and the extreme brilliance of the phenomenon. This explanation is quite unacceptable for II (theoretical bearing 179°). III cannot have been the primary parhelion of 46° owing to the high altitude, but might have been the secondary parhelion of 2 × 22°.

I have taken the liberty above of introducing the word 'meteoroptical' in place of 'meteorological optical', which is cumbersome.

PAUL WHITE.

University of Reading.
Sept. 30.

## Antiquity of Man in Australia

IT was very gratifying to read Prof. F. Wood Jones' article and also Dr. F. E. Zeuner's appraisement of the Keilor skull discovery[1]. In Australia, the significance of the skull has only been appreciated in part, a fact which can largely be explained by preoccupation with the War. Mahoney's scholarly memoir[2] has indicated that, even if his altimetric estimation of the age of the skull is not accepted as final, every endeavour should be made to conserve all relevant data available.

The deposit in which the skull was found is very limited, probably of less than an acre; nevertheless the site of the discovery is still being exploited as a sandpit, and although contemporaneous deposits no doubt will be found, no attempt has been made to preserve the site for a thorough scientific search.

Furthermore, I am given to understand that the sand contractor who found the original skull had in his possession another skull, bones and possibly artefacts, which seemingly will be lost to the scientific world.

Zeuner expresses the hope that "the Keilor discovery will encourage further search for early man in Australia". It is suggested that a more urgent task for Australian science is not so much archæological as anthropological, for in the sociology of the few remaining tribalized aborigines we have the key to our own social evolution which, even if the aborigines themselves do not die out, will, in a matter of a few decades, be irretrievably lost.

The riddle of the world-wide mother-in-law taboo[3] can only be solved by assuming social conditions in the past similar to those of the Australian aborigines, and it has been indicated how man's earliest social evolution must have been determined by the progressive avoidance of incest. The structures of Australian societies show how this avoidance was obtained by the introduction of taboo and exogamy[4].

It is therefore to be regretted that in the southern hemisphere there has been during the past few years a marked swing away from the study of the Australian aborigines towards the study of the more colourful island people to the north of Australia, whose societies will still be virtually intact when those of the Australian aborigines will be, like the Tasmanians, a thing of the past.

## A New England Naturalist

IN connexion with the interesting and entertaining review[1] by Sir D'Arcy Thompson of Dr. Barbour's book "A Naturalist at Large", it is worth putting on record that the Zoo has had two specimens of the Páca rána (*Dinomys branickii*) from South America during the past twenty years. The first was presented by Mr. Herbert Whitley in June 1925 and the second was purchased from a dealer in September 1929.

At death, both bodies were preserved, the former being sent for dissection to Dr. A. B. Appleton at Cambridge, the latter to Tring Museum at the request of the late Lord Rothschild.

G. M. VEVERS.

## Photochemistry in Retrospect

DR. IREDALE[1] discusses in his retrospect on photochemistry the surprising fact that Einstein's Law of Photochemical Equivalence seems to be almost forgotten by modern photochemists. This oblivion is still more astonishing if one remembers the role of the law in general chemistry.

From the beginning, it was quite clear that any experimentally established failure of the law in a complete photochemical reaction was due to purely chemical secondary reactions. These are independent of the photochemical primary processes, which are without exception controlled by Einstein's Law. E. Warburg's[2] finding that not one molecule as expected but *two* molecules of hydrogen iodide are decomposed by *one* light quantum led him to the fundamental assumption of the interaction of short-lived hydrogen and iodine atoms in the secondary reaction chain. This chain reaction is the model for all modern conceptions of chemical and photochemical reaction kinetics, which operate with free atoms or radicals.

# RESEARCH ITEMS

### Blood Sugar Levels in the Bengal Famine

DR. M. L. CHAKRABARTY, at the Campbell Medical School, Calcutta, has measured the blood sugar in a series of starvation cases admitted to hospital during the recent famine. In a communication to *Nature*, he states that some surprisingly low figures were found; the lowest recorded was 20 mgm. per 100 c.c., and this case recovered under treatment. In a normal individual, definite symptoms of hypoglycæmia occur when the blood sugar falls below about 70 mgm. per 100 c.c.; but these starvation cases, although weak and lethargic, with profound depression of all bodily activities, never exhibited any of the typical nervous symptoms of hypoglycæmia in spite of their extremely low blood sugars. The absence of hypoglycæmic symptoms was probably due to the slow and insidious onset of the hypoglycæmia; in such cases of 'chronic' hypoglycæmia it seems that the nervous system has time to adapt itself to the low sugar level. Biochemical investigation of these cases is proceeding and the main interest so far is the demonstration that life can continue, albeit at a low ebb, with a blood sugar of only 20 mgm. per 100 c.c.

### Immunization against Malaria

H. R. JACOBS (*Amer. J. Trop. Med.*, 23, 597; 1943), working on immunization against malaria, has shown that, in ducklings, the subcutaneous injection of saline-insoluble residues of *Plasmodium lophuræ*, mixed with a staphylococcus toxoid, give practically 100 per cent immunity to malaria. The substance used is "an extract of protamide plasmodial precipitate insoluble in saline solution". It appears that such plasmodial substances insoluble in saline contain antigenic material which is effective, and that by addition of bacterial toxin its efficacy could be increased sufficiently to give promise of a wider application. F. F. Schwentker and F. C. Comploier (*J. Exp. Med.*, 70, 223; 1939) have shown that a toxoid combined with a non-antigenic material served to make it antigenic. Jacobs does not claim that immunity is produced, but that effective protection against malaria is obtained; and he feels that the way is opened for the preparation of a good vaccine which will provoke an immunity so powerful that overwhelming doses of the parasites will be neutralized quickly.

### Poisoning by Tetrodon Fishes

WARREN HAROLD YUDKIN in an interesting paper discusses and summarizes information on the poisoning properties of the Tetraodontidæ or puffer fishes (Tetrodon Poisoning. *Bull. Bingham Oceanographic Coll.* Peabody Museum of Natural History, Yale University, 9; 1944). Poisoning by various fishes belonging to this family has been known for centuries and much has been written about it, as is shown in the present paper. A certain amount of research has been done, especially by the Japanese on species of *Tetrodon*. These fishes are eaten to a large extent in Japan and a number of people die of poisoning every year. Macht and Spencer (1941) have recorded interesting work done on *Spheroides maculatus*, the Atlantic puffer. This fish has recently attained market status as a result of the increased utilization of 'trash fish'. Evidence is provided that toxic substances of many Tetraodontidæ are located chiefly in the gonads and liver and may vary with the breeding seasons. *Spheroides maculatus* has been eaten for some time in various regions, with few, if any, reports of ill-effects, and it is probable that when properly cleaned it is not ordinarily toxic. Experiments are now being conducted at the Bingham Oceanographical Laboratory on this fish to ascertain whether it can be toxic under certain conditions, and it is strongly recommended that similar detailed researches should be made in other localities.

### Diphyllobothriidæ in the South Wales Trout

FURTHER reference to the occurrence of larval stages of Diphyllobothriidæ in trout in South Wales and in the Dublin area (see *Nature*, Aug. 5, p. 185, and Aug. 26, p. 267) is made by K. Unsworth (*Brit. Med. J.*, 385, Sept. 16, 1944), who says that a full account of the life-cycle of the parasite found in the trout in South Wales will be published in the near future. The life-cycle has now been successfully completed experimentally in the dog, with *Cyclops* and the stickleback (*Gasterosteus aculeatus*) as intermediate hosts. Discussing the view of M. D. Hickey and J. R. Harris that cormorants and seagulls are the naturally infested definitive hosts of the parasite in the Dublin area, Unsworth suggests that the trout in South Wales were infested with two distinct species, one of which develops in an avian and the other in a mammalian host.

### Naked Pigeons

"PIGEON courtship, with its strutting, cooing and puffing out of feathers is an interesting performance. When there are no feathers to puff or to clothe the performer it becomes a ludicrously macabre travesty of a dance." L. Cole and R. D. Owen (*J. Hered.*, 35, 3; 1944) describe such a case which results from a simple recessive gene. The accompanying photographs suggest a complete picture of the Dodo in "Alice in Wonderland". The interest of the case is that all the normal reactions of attempting to fly, to parade before the female and to fight with the wings are present. As a result of the absence of feathers the birds do not retain the heat and must be kept in artificial warmth; they are infertile as males since they are unable to balance properly in mating. Artificial insemination has been successful, but is laborious. There was no inferiority complex shown by featherless pigeons and artificial clothing was deeply resented.

### Occurrence of Epilepsy in Cattle

A YOUNG brown Swiss bull showed signs of epilepsy at six months old. Tongue chewing, slight foaming at the mouth and collapse in coma were the chief symptoms. Injections of calcium gluconate relieved the symptoms in about fifteen minutes. F. W. Atkeson, H. L. Ibsen and F. Eldridge (*J. Hered.*, 35, 45; 1944) describe this case and the progeny derived from this bull. There were thirty-seven offspring, of which twenty-three were apparently normal, thirteen were epileptic and one died at birth. There are indications that this autosomal dominant is of recent origin. The attacks take place in the first two years of life; as the animal gets older, the intensity and frequency of the attacks varies considerably and in some cases may not be detected.

### Oxidation and Mechanism of Action of Mutagenous Factors

ACCORDING to the current biophysical theory, a mutation caused by X-irradiation is regarded as a

result of direct action of a secondary electron upon an atom in a genetically significant structure. Investigations undertaken by I. A. Rapoport in the Institute of Cytology of the U.S.S.R. Academy of Sciences (*J. Gen. Biology*, Moscow, 4, No. 2; 1943) suggest that the phenomenon may be more complex. It appears that the mutation effect of short-wave irradiation is due to the appearance in the irradiated cell of a substance inducing mutations. Such a substance is possibly ozone, formed in the cell from oxygen as a result of irradiation. Combined action of iron (in the larval food of *Drosophila*) and X-rays resulted in a marked increase in the percentage of mutations. This stimulating effect of iron on the mutation process cannot be explained on the basis of biophysical theory but it accords well with the fact that physiological action of ozone is stimulated by iron. The chemical action of X-rays and of the activated oxygen is similar in some respects. The disturbance of continuity of a chromosome thread due to irradiation may be compared with the rupture of ozonides at the site of the unsaturated bond. The presence of such unsaturated bonds in the chromosome would make it possible to interpret synapsis and crossing-over as phenomena of labile polymerization and depolymerization. Since very active forms of oxygen are formed regularly in the course of normal metabolism, they may constitute an important factor in a spontaneous mutational process.

### Non-Coherent Scattering in Astronomy

A DETAILED review by Spitzer has appeared (*Astrophys. J.*, 99, 107; 1944) of a paper by Houtgast of Utrecht on the variations in profile of strong Fraunhofer lines across the sun's disk, and some remarks are made (*ibid.*, p. 1) by the same author on the theory of non-coherent scattering, stimulated by Houtgast's work. The observational material in Houtgast's paper is by far the most extensive and homogeneous yet obtained; but divergences between the measured profiles and those previously published suggest the presence of systematic differences which may be instrumental or may be real, caused perhaps by variations in solar activity. The centre-limb variations found in the far wings of absorption lines are compared in turn by Houtgast with what would be expected for pure absorption, pure extinction and pure scattering. It is found that coherent scattering does not adequately represent the observations even qualitatively, especially in the ultra-violet lines, for which the absorption wings should vanish towards the limb and be replaced by emission wings close to the limb. It is therefore suggested that the dominant process in the formation of strong absorption lines is non-coherent scattering, a phenomenon which arises when the selectively scattered radiation is first captured in the usual way and then re-emitted with a slightly different wave-length, and which appears as pure absorption in the wings. Spitzer's own investigation shows that non-coherency may be expected to occur, partly or wholly, in the scattering process which forms almost all absorption lines of astrophysical importance. The effect of the process on line profiles is not very large: no major change in the curve of growth is to be expected, but the cores of strong lines will be sharper than predicted on the assumption of coherent scattering, especially away from the limb. This is in qualitative agreement with accurate profiles determined interferometrically for the *D* lines in the sun, and with the sharp cores of the hydrogen lines in *A*-type stars. Further study of this almost unexplored field promises to be interesting.

### Relation between Magnetic Storms and Solar Activity

C. W. ALLEN, Commonwealth Solar Observatory, Canberra, has described a statistical investigation of the influence of solar flares and sunspots on terrestrial magnetic storms (*Mon. Not. Roy. Astro. Soc.*, **104**, 1; 1944). The magnetic data cover the period 1906–42, and up to 1937 international character figures were employed; during 1938–42, *K*-index daily sums were used. In the period 1906–43 there were 2,800 disturbed days, and these were divided into four groups on the basis of recurrence tendency, as shown in 27-day charts. There is some evidence to support the view that great magnetic storms are caused by chromospheric eruptions, the time interval between the eruption and the maximum of the great storm being approximately 1½ days. Eruptions are also responsible for some smaller storms with a 2½-day interval. Smaller storms tend to recur at intervals of 27 days, which betrays their solar origin, and shows that there are regions on the sun's surface, known as Bartel's '*M* regions', not distinguished by any markings, which are associated with these minor geomagnetic disturbances. A period of about three days is required for *M*-region particles to travel from sun to earth. The *M*-region is considered to be an emission coming continuously from almost all the sun's surface, and constrained to move in streams by forces in the sun's atmosphere. The persistence and changes of the recurrent magnetic storms would then be due to the continuity of these streams. A close relationship has been found to exist between sunspots and coronal plumes, though the foci of the plumes do not coincide exactly with sunspots. While the plumes come from areas that in general surround or are close to group spots, the 1919 eclipse did not show this relationship, thus proving that the large groups and spots are not invariably connected with one another.

### Meteor Observations during 1941–42

MOHD. A. R. KHAN (*J. Hyderabad Acad.*, Studies No. 6; 1943) has discussed observations during two years of shower meteors and exceptionally bright meteors. The shower meteors were the Quadrantids, Lyrids, $\eta$ Aquarids, $\delta$ Aquarids, Perseids, Orionids and Geminids. In 1941 the Quadrantids and Lyrids were extremely scarce, only one of each being observed, but the other showers were fairly active. In 1942 moonlight and other hindrances prevented systematic observation of the first four showers, and few of the meteors recorded during the Perseid and Orionid period belonged to either of these showers. In addition to some exceptionally bright meteors emanating from the showers referred to, 28 more were observed during the two years. In 1941 during a watch totalling 57h. 02m. over 114 nights, 914 meteors were seen, and in 1942 a total of 44h. 54m. was spent on 118 nights, during which 710 meteors were seen. The questions of persistence of streaks and of their colour and size are discussed. Dryness of the air, like clearness or dust-free conditions, seems to determine the visibility of enduring trains. The author's observations lead him to conclude that the drier the air is in certain regions the more likely will enduring streaks be seen. In addition to this factor, it is suggested that the electrical condition of the upper atmosphere is also important, because it is known that ionization plays a very important part in the development of meteor trains.

# SURFACE TENSION AND THE DEGENERATION OF NERVE FIBRES

By J. Z. YOUNG
Magdalen College and Department of Zoology, Oxford

A NERVE fibre is an immensely elongated cylindrical cell the content of which is a viscous fluid. Around it there is often a semi-fluid covering, the myelin. Now Plateau[1] showed that a cylinder of liquid only remains stable under its surface tension if its length is less than its circumference. High viscosity and other factors may allow cylinders of somewhat greater length, but as the length is increased a point is reached at which small deformations are not corrected by the surface tension, which rather causes the cylinder to acquire an unduloid outline and break into droplets. Instances of the operation of this principle are common in Nature[2]; for example, the protoplasm of plasmolysed root hairs assumes an unduloid form.

There are many indications that such surface forces operate in nerve fibres. For example, during the degeneration of the peripheral section of a severed nerve fibre the myelin and axon lose their cylindrical shape and form a series of ovoid segments. The first sign of this 'degeneration' is the assumption of an unduloid outline by the myelin, followed by a breaking into segments, long at first, then shorter and shorter, until a series of spherical droplets remains. The process goes on very slowly and in a rabbit's nerve examined three or four days after severance all stages can be seen. During the separation of the segments a neck is first formed, and this then breaks to form 'Plateau's spherules', which appear with a regularity almost equalling that of the experiments which Plateau himself and Darling[3] made with equidense liquids (Fig. 2).

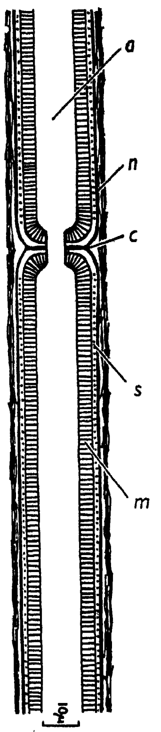

Fig. 1. Diagram of a longitudinal section of a portion of a peripheral nerve fibre; *a*, axon; *m*, myelin; *n*, neurilemma; *c*, 'cementing disc' at node; *s*, protoplasm of Schwann's cell.

The situation is of course complicated by the fact that the axon and myelin are enclosed in a tube composed of the protoplasm of the cell of Schwann and the neurilemma and endoneurium (Fig. 1). The last two form a wall which is moderately rigid and little elastic. The Schwann cell forms a fenestrated membrane between the myelin and the neurilemma. It seems probable that the tube wall as a whole is permeable to water, and that the myelin does not wet it. There is therefore little difficulty in the formation of new surfaces and segmentation of the contents of the tube.

If surface tension causes the isolated nerve fibre to break up, what is the force emanating from the cell body which normally maintains its integrity? It was suggested[4,5] that the fact that material flows from the central but not the peripheral end of a severed nerve fibre indicates that there is an intra-axonic turgor pressure and flow. Weiss[6] has recently adopted a similar view in showing that there is a continual growth of axons, leading to a damming of axoplasm behind a constricted point on a nerve. No one has yet actually measured the rate of movement of the axoplasm; but it seems likely that it takes place continually, if slowly, presumably forcing out material over the surface of tho fibre. It is possible that it is the resulting pressure, blowing up the fibre from inside, which maintains the cylindrical outline against the surface tension forces. If this is correct it might be possible to prevent degeneration in a peripheral stump by providing a substitute for the normal pressure.

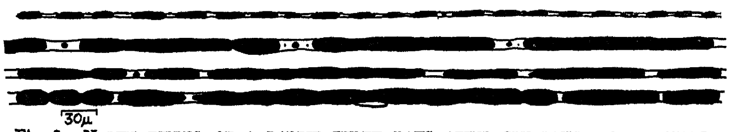

Fig. 2. Nerve fibres of a rabbit three days after severance, seen after staining with osmium tetroxide. Note unduloid outlines and separation into ovoids with primary and secondary Plateau's spherules between.

The tendency to assume an unduloid outline is certainly very strong, and probably operates even during the normal life of a nerve. Fibres teased carefully in Ringer's fluid show various degrees of departure from a strictly cylindrical shape. There is a close topographical relationship between the unduloids and the incisures of Schmidt-Lanterman (Fig. 3). These oblique cracks in the myelin always lie in the region of concavity of a wave. Now the myelin consists of coaxial sheets of orientated phosphatide and protein molecules[7], and in some stages of incisure development the breaking of these lamellæ can be clearly seen, especially in the troughs of the unduloid. Longitudinal stress increases the incisure[8]. The material of the myelin is evidently very peculiar if it can flow and yet break in this way, and further investigation is necessary. Fig. 4 suggests that the broken edges of the lamellæ constitute the 'spiral apparatus of Golgi-Rezzonico' which appears to occupy the cleft.

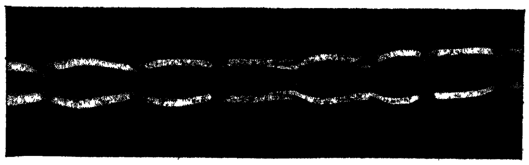

Fig. 3. Nerve fibre of rabbit isolated in Ringer's solution and photographed in polarized light. (× 600.)

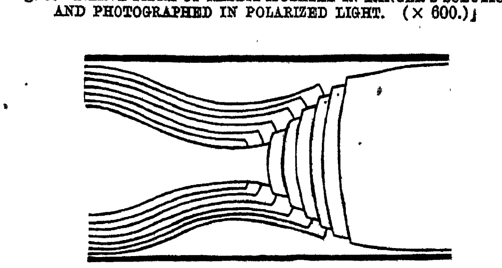

Fig. 4. Diagram to show result of assumption of unduloid outline by a nerve fibre, breaking the lamellæ of the myelin to form an incisure.

Ranvier[9] suggested that the myelin can be considered to be included within its Schwann cell as a fat droplet in a fat cell, and hinted at the possible importance of its surface tension. Several observations indicate that each whole internodal segment can be regarded as a drop, elongated to a length of as much as 1·2 mm. on a mammalian nerve fibre 20μ in diameter (Fig. 5). If a piece of rabbit's nerve is placed in hypotonic Ringer's solution (say 0·6 or 0·3 per cent) at 37° C. it soon becomes very turgid, and material is expelled from the ends to form mushroom-like outgrowths. Incidentally, as Ranvier pointed out in interpreting the effects of treating nerves with water, this provides further evidence that the contents of a nerve fibre are fluid and can move longitudinally. At the same time, the myelin shows remarkable movements, flowing over the surface of the axon, which it leaves bare for quite long stretches at the nodes (Fig. 6). Later the myelin may subdivide into shorter segments. These phenomena can be explained as follows. The swelling is mainly due to osmosis across the membranes at the surface of the axons, the latter increasing in volume. This produces a tendency to increase the area of the myelin, which rounds up under its surface tension, leaving the axon bare at the nodes.

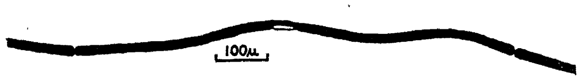

Fig. 5. NORMAL NERVE FIBRE, SHOWING A SINGLE INTERNODE WITH THE SCHWANN CELL NUCLEUS AT ITS CENTRE.

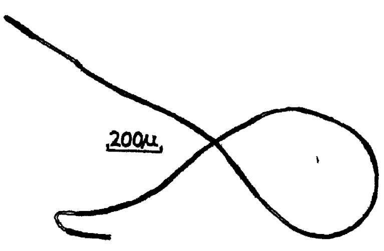

Fig. 6. FIBRE WHICH HAD BEEN FOR THREE HOURS IN DILUTED RINGER'S SOLUTION (0·3 PER CENT), SHOWING RETRACTION OF THE MYELIN AT THE NODES.

The experiment gives a clue to the factors controlling node-length during development. The myelin is laid down as the fibre is increasing in diameter, being first formed in the neighbourhood of the Schwann nuclei, which are spaced at more or less regular intervals along the fibre[10]. In the early stages, quite long regions of axon are left bare at the nodes. As the fibre grows in length and diameter the myelin continually tends to round up, as in the experiment with hypotonic solutions, and this prevents the individual segments from running together to make a continuous cylinder. By the time growth in length and diameter have ceased, the inturning of the neurilemma and the presence of a special 'cementing disc' (*c*, Fig. 1) at the node maintain the separation. During growth the segments of myelin increase in length but not in number. The first fibres to medullate are those which will ultimately become the largest, and these thus come to have the longest segments, whereas the smaller fibres, medullating later, have proportionately shorter and more numerous internodes. In confirmation of this hypothesis Mr. A. Vizoso, in this department, has recently found that after regeneration of an adult nerve for periods of more than a year, the internode-lengths remain short, even on the largest fibres. The internode-length is therefore not a function of diameter as such, but is determined by the relation between time of medullation and subsequent growth. Drs. F. K. Sanders and D. Whitteridge measured the conduction velocity of the nerves studied by Vizoso and found it similar to that of normal fibres of the same diameter, in spite of the short segments. Evidently conduction velocity does not have a close relationship to internode-length. Although the function of the nodes remains obscure, it may be that they serve to prevent movement of the fluid within the fibres. The aggregate of forces produced by the surface tension at the ends of a series of droplets is considerable.

Fibres of the central nervous system are usually without nodes, and lack the definite tubes which are present in peripheral nerve, no doubt to meet the stresses imposed by movement. In the absence of the tubes the myelin of the central fibres presumably wets the material which surrounds it, and therefore does not divide into segments. In confirmation of this is the fact that the central fibres rarely show incisures. They may develop an unduloid outline, but then proceed to break outwards, forming spheres and other figures at the crests of the waves.

There is obviously much to be done to confirm and extend this view of the nature of nerve fibres. The presence of the unduloid outlines and the forms seen during degeneration show quite decisively that the axon and myelin behave partly as liquids the surface tension of which affects their shape, and it seems likely that the intra-axonic pressure has an important influence on the stability of the fibre.

## ENGINEERING AND INDUSTRY IN RECONSTRUCTION

IN his inaugural address on October 12 to the Institution of Electrical Engineers, Sir Harry Railing made an assessment of the extent to which engineers, particularly those in the electrical industry, can and should contribute to the solution of some post-war problems. A broader understanding of sociological problems has become essential for the engineer, for the products of his technical skill affect every human individual and human organization. A greater understanding of science in general and engineering in particular has become essential for every citizen, not necessarily in the form of detailed knowledge, for a better comprehension of life. In the logical pursuit of his mission to help the post-war world, the engineer must therefore teach the principles which underlie his work, in the hope that they may be accepted and applied.

As to some of the more specific contributions which engineers can make towards solving international and

national post-war problems, we cannot envisage either an individual or an organization within a country, or a country within the community of nations, which will be able in future to maintain any monopoly in production, unless it can forge ahead in new developments and products, or can lead in quality or in production cost.

It is to-day more than ever essential that every individual in industry should be as highly developed and receive as good a general education and training in his handicraft or profession as possible, and that he should be taught a deep sense of personal and collective responsibility. This means not only education in engineering, but in team-work as well; and such education must stress the fact that anybody who accepts more from the team than he contributes, who seeks to take more out of life than he gives, constitutes a liability rather than an asset; on the other hand, every man who gives more than he receives creates values and therefore leaves something of positive value to his fellow workers at the end of his career.

Coming to the part played by industrial associations, it is now generally acknowledged that there is an ever-increasing volume of interests common to all members of a particular industry, the furtherance of which can be undertaken by such associations with great advantage both to the industry itself and to the market which it serves. Properly constituted associations have made great contributions to ordered industrial progress, and proved themselves a socially beneficial instrument through such activities as the standardization of specifications and common parts, the pooling and exchange of patents and manufacturing experience, a measure of joint research, the standardization of trading conditions, the collection of statistical information, the maintenance of good relations with other industries, and negotiations with Government departments and with labour.

So far as the position of industry within the State is concerned, we may start from two premises which to-day are generally accepted. The interests of the individual, of a group, of a class must all be subject to the proved interest of the community. With this reservation, however, a community will be most successful, advance furthest, and obtain the highest degree of development, if it allows the utmost freedom of thought, action and development to the individual and to groups of individuals. The action of any central authority should be not so much to instruct people what to do as to restrain them from actions which might be prejudicial to others.

Regarding the influence of wages, if wage-rates in a country increase more than the normal cost of living, there will generally be an increase in the volume of articles produced, owing to an increase in the effective demand. Also, with increasing wages, taken by themselves, the cost of the product increases, and therefore the quantity of goods which can be sold in the export market decreases; or alternatively, there is an increase in the cost of raw materials and food bought in exchange. There is, therefore, a wage limit which, for a country such as Great Britain, cannot be exceeded so long as other countries lag far behind its standard of living. It is consequently of vital concern to us to-day that the living conditions of less advanced countries, especially those which have become industrialized, should approach our own, and so bring about an expansion of world demand and the possibility for us to advance further, or at any rate to maintain our own standard.

The essentials needed to maintain the advance of British industry, therefore, are first of all, measures that assure the maintenance of any lead we can gain by increased research, better education, and the development of the more complicated and advanced problems; secondly, the provision of increased capital assistance for each worker, whether it takes the forms of increased power supply, tool equipment, transport facilities, improved lighting, or working conditions in general; and thirdly, the enlightenment and education of management and labour, and indeed of every worker, both as regards his own contribution and that of each partner with whom he must work; finally, any measures which help to increase the volume of our export business, and especially those which create expansion of world demand by raising the standard of living in backward countries.

## THE LISTER INSTITUTE OF PREVENTIVE MEDICINE

THE report for 1944 of the Governing Body of the Lister Institute of Preventive Medicine again records the wide scope of the work of members of its staff. The death of Prof. W. W. C. Topley has been a severe loss to the Council, and the Governing Body also lost the services of Sir Joseph Arkwright, who has retired after long service both in administration and research. Many of the staff remain in their war-time stations in laboratories in Cambridge, Oxford and elsewhere, and many of them are serving on committees set up by the Medical Research Council. Bacteriological and immunological researches in progress include work on the anti-proteus *OX* 19 serum for the treatment of louse-borne typhus, trials of which have been carried out in North Africa in co-operation with United States Army medical authorities. All the six severe cases treated with it recovered. The typing of typhoid, paratyphoid and food-poisoning bacilli with the *Vi* bacteriophage has been continued and a hitherto unknown *Vi*-phage type of the typhoid bacillus has been identified. The study of dysentery prophylaxis is making good progress and valuable work is being done on the immunology and nuclear structure of the gas gangrene organisms and on hyaluronidase. In collaboration with the Stormont Laboratory of the Ministry of Agriculture, Northern Ireland, outstanding contributions have been made to the study of trichomoniasis. Biochemical studies are in progress on specific blood-group substances, on the action of various bacterial toxins and on gramicidin, while work on low-temperature drying of biological materials and on fœtal and maternal serum is making good progress. The work on the large-scale processing of human serum and plasma for transfusion has produced valuable results. Problems arising in the kaolin processing of plasma have been solved and the Serum Unit has been filtering the entire output of the London blood transfusion depots before sending it on to Cambridge for freeze-drying.

Other work includes the cultivation of the virus of vaccinia, work on sex and other hormones and nutritional studies. The work done with the aid of volunteers at Sheffield has indicated how large are the vitamin A reserves of the liver of healthy human adults. Studies of the nutritive value of the potato have shown that potatoes are a rich source of vitamin

A and that, weight for weight, the nitrogen in potatoes has a biological value at least equal to that of whole wheat, although only about half of it is in the form of protein. It is believed that there is a supplementary action between the protein and non-protein nitrogenous substances in the tuber which is probably attributable to the amino-acids present among the latter, although the amides and basic nitrogenous compounds probably also take part.

When the nutritional state of housewives in Oxford and of women working in factories there was studied for a year, it was found that their nutritional state deteriorated very little, although that of the workers deteriorated more. There were no clinical signs of special nutritional defects, except that 25 per cent of the workers showed enlargement of the thyroid and 36 per cent of them had dental fluorosis: the incidence of both these conditions is high in north Oxfordshire.

The Institute continues to perform that valuable service, the maintenance of the National Collection of Type Cultures, for which more accommodation has been provided. Everyone will hope that very soon the staff of this Institute will be able to re-assemble in London and at Elstree to continue, in the closer collaboration made possible by that return home, the valuable work which is here so modestly reported.

G. LAPAGE.

# FORTHCOMING EVENTS

### Saturday, October 22

BRITISH RHEOLOGISTS' CLUB (at the University, Reading), at 2.30 p.m.—Annual General Meeting. Discussion on "The Measurement of Tack" (Introductory Papers by Dr. N. A. de Bruyne and Dr. R. F. Bowles).

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. Nellie B. Eales: "Some Aspects of the Malaria Problem".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield, 1), at 2.30 p.m.—Mr. A. Preece: "The Oxidation of Steels in Furnace Atmospheres".

### Monday, October 23

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Engineer's Part in Certain Post-War Problems" (to be opened by the President).

### Tuesday, October 24

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Mr. J. E. Wright: "The Application of the Universal Decimal Classification to Telecommunication Literature—Some Suggestions for Developing the Tables to meet Modern Requirements"; Mr. L. S. Harley: "Document Classification in a Limited Field—Radiocommunication and Allied Subjects".

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Mr. C. F. Sayers: "Quartz Crystals and some of their Applications, with Specific Reference to Telecommunications".

ROYAL INSTITUTE OF CHEMISTRY (LEEDS AREA SECTION) (joint meeting with the LEEDS UNIVERSITY CHEMICAL SOCIETY) (in the Chemistry Lecture Theatre, The University, Leeds), at 6.30 p.m.—Prof. J. W. Cook, F.R.S.: "Some Chemical Aspects of Cancer Research".

### Tuesday, October 24—Wednesday, October 25

BRITISH SOCIETY OF ANIMAL PRODUCTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10.30 a.m.—Discussion on "The British Sheep Industry".

**Tuesday, October 24**

Prof. R. G. White: General Survey; Mr. D. H. Dinsdale: "Hill Sheep"; Mr. T. L. Bywater: "Sheep for Long Leys"; Mr. J. F. H. Thomas: "Arable Sheep".

**Wednesday, October 25**

(Joint Meeting with the INSTITUTE FOR THE STUDY OF ANIMAL BEHAVIOUR). Mr. John Hammond, Jr., Mr. L. R. Wallace and Dr. Nancy Palmer: "Current Investigations relating to Sheep"; Dr. J. E. Nichols: "The Behaviour of Sheep Browsing under Drought Conditions"; Prof. Johnstone-Wallace: "The Grazing Habits of Beef Cattle"; Dr. K. L. Blaxter: "Food Preference and Food Habits in Dairy Cows".

### Wednesday, October 25

INSTITUTE OF FUEL (MIDLANDS SECTION) (at the James Watt Memorial Institute, Birmingham), at 2.30 p.m.—Mr. L. C. Southcott and Mr. D. W. Rudorff: "Superheaters for Water Tube Boilers" (Précis and Discussion).

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Mr. W. B. Adam and Mr. D. Dickinson: "Diagnostic Methods in Problems concerned with the Corrosion of Cans".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (joint meeting with the PLASTICS GROUP OF THE SOCIETY OF CHEMICAL INDUSTRY) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. Willis Jackson and Mr. J. S. A. Forsyth: "The Development of Polythene as a High-Frequency Dielectric".

INSTITUTE OF WELDING (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Welding in British Industry after the War" (to be opened by Mr. H. I. Hodgson (Automobiles and General Engineering); Mr. C. S. Lillicrap (Shipbuilding); Mr. H. N. Pemberton (Pressure Vessels); Dr. H. Sutton (Aircraft)).

ROYAL INSTITUTE OF CHEMISTRY (DUBLIN SECTION) (at University College, Upper Merrion Street, Dublin), at 7.30 p.m.—Mr. H. G. Leonard and Mr. P. Whelan: "Spectrographic Analysis".

### Friday, October 27

INSTITUTION OF CHEMICAL ENGINEERS (CHEMICAL ENGINEERING GROUP) (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1), at 3 p.m.—Sir Alexander Gibb, G.B.E., F.R.S.: "Hydro-Electric Development in Great Britain and its Influence on Chemical and Allied Industries" (Fifth Hinchley Memorial Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. Edward Reeve: "The Influence of Engineering on Social Advancement".

INSTITUTE OF FUEL (SCOTTISH SECTION) (at the Royal Technical College, Glasgow), at 5.45 p.m.—Mr. W. J. Skilling and Dr. M. McGregor: "Scottish Coal Resources".

### Sunday, October 29

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (joint meeting with the ASSOCIATION OF AUSTRIAN DOCTORS) (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 11.30 a.m.—Dr. F. Bergel: "Life Saving and Life Preserving Plant Products".

# EDUCATION BEFORE DEMOBILIZATION

AMONG the limited number of benefits conferred on us by the War is the growth of the educational services in the Armed Forces. The work carried out has already been referred to in some detail in these columns[1]. The schemes have developed along different lines in the three Services, but in each case the amount and quality of work that is being done has reached proportions which would undoubtedly astonish those who were familiar with Service conditions in the War of 1914–18. In the Army, for example, a compulsory form of education has now been conducted for four years, and has grown into what must be one of the most searching and wide-ranging experiments in adult education that has yet been attempted. Soldiers and auxiliaries have been given opportunities of voluntarily studying subjects as far apart as chiropody and Chinese, music and metallurgy; the element of compulsion has been applied to the discussion of current problems and the way in which good citizens are produced. These miscellaneous activities have not been without effect, and it is not surprising, therefore, to find that Service education departments have been preparing even more comprehensive programmes for the release period which will begin when Germany is defeated. The Army and the Royal Air Force schemes were announced at the beginning of October, and it is expected that a statement will be made on behalf of the Royal Navy in the near future.

In the R.A.F., officers, airmen and airwomen, who have not been selected for regular service in the post-war period, are to be given a pre-release preliminary training to prepare them for return to civilian life, under a scheme which will be known as the Educational and Vocational Training Scheme. This will form part of the Government plan for the re-settlement of personnel after release from the service. The training will consist of three main types, re-settlement, educational and vocational, and will be part of an obligatory programme which will take up an average of six hours training time a week. Of these six hours, one will be devoted to re-settlement training, and run mainly on discussion-group lines and designed to give both background knowledge on post-war problems and information on the fundamentals of citizenship. The series of booklets, produced by the Army and called "The British Way and Purpose", will be used to deal with particular aspects of citizenship. To supplement the discussions, additional methods of instruction such as lectures, broadcasts, films, etc., will be used.

Educational training will be provided at secondary and higher levels and will allow R.A.F. personnel to improve both their general educational standards and their qualifications for civilian employment. At the secondary level, training will be devoted mainly towards the Forces Preliminary Examination. This Examination will be introduced to meet the needs of men and women who wish to prepare themselves for subsequent entry to certain universities, the Civil Service or some of the professions. Success in the

Examination will allow the candidate to be considered for entry to a university or to be exempted from the preliminary examination of the professional body concerned. It will in no way replace existing means of qualifying for entry to universities. Higher educational training will be available for those who have reached matriculation standard, and will normally consist of individual private study under the supervision of education officers and instructors.

Vocational training will be provided for civilian occupations only when the prospects of employment are favourable enough to merit training. Frequently, this training will consist of the conversion of a skilled R.A.F. tradesman into a tradesman fitted for a job in civilian life. In other cases, the aim will either be to improve existing civilian occupational qualifications or to give a man or woman with no qualifications the groundwork on which more specialized vocational training may be built outside the service. Since there is almost certain to be a great demand for training for jobs, it will scarcely be possible to provide resident specialist instructors at each station. Instead, pools of specialist instructors in technical and professional subjects will be maintained at some central station and will visit units to meet current requirements.

The training for vocations will be worked out in the following way: (1) There will be practical instruction and exercises on stations supervised by visiting instructors. (2) There will be courses in the basic theoretical subjects necessary for groups of civilian occupations. (3) Conversion courses will be arranged in station workshops. (4) When other facilities are not available, study syllabuses and text-books will be provided. (5) Close liaison will be maintained with civilian authorities, and attendance at classes in local technical colleges and schools will be encouraged.

The scheme announced by the War Office is less ambitious than that for the R.A.F. In a pamphlet called "Brush-up for Civvy St.", which has been issued by the Army Bureau of Current Affairs, the plan is modestly described as a means "for making up, so far as possible, those arrears of education and training which are a part of the debit side of war service", and the hope is entertained that the scheme will make an important contribution to the morale and community spirit of the Army during a difficult period.

The scheme itself is described in general terms in the pamphlet; the latter will be used immediately by regimental officers to acquaint their men with the main features. But these officers are categorically told that they must make it quite clear to the men that the educational scheme to be introduced in the release period is not intended to prepare them for a gilt-edged, guaranteed job. The business of getting soldiers into jobs, or getting them trained for jobs, will be mainly the duty of the Ministry of Labour. The Army itself can do no more than provide the men and women who are awaiting release with some kind of preliminary training which will be useful to them when they are demobilized. For those who need it, "it will teach the A.B.C. of industry and commerce, so that they can go out and learn the language". For the soldiers who do not require any preliminary vocational training, opportunities will be given to pursue hobbies and interests which will broaden their cultural horizon. Individuals whose professional studies have been interrupted by the War will be given a new chance to take up the threads by means of correspondence and other courses.

The varied principles of the scheme are described under eight headings. It will be compulsory, that is, it will be an obligatory part of the working time-table. This is merely an extension of the present system, but under the new regulations, educational training will be given more emphasis and more time. Variety will be introduced into the scheme in that the troops will have a reasonably wide choice in what they want to study. The third principle—that participation in the scheme as instructor or as one of the instructed will in no way affect the individual's chances of demobilization—will be one that will wreck the scheme at the outset unless it is said loudly and often. To fit in with military organization the new scheme will dovetail into the existing pattern of Army administration and procedure. Fifthly, the scheme will be co-educational and will apply equally to men and women whenever possible. For obvious reasons, it will not be possible to put the scheme into operation at any predetermined, fixed time; according to the pamphlet, "formations will 'lay on' the scheme at different times, depending on what part of the world they are in and what their other circumstances are (e.g. static, operational)". The close collaboration with the civilian educational bodies which already exists will be continued, partly for its direct and intrinsic value to Army education, and partly because, having had experience of what the civilian system can provide, soldiers may be more stimulated to use it after the War. Lastly, it is emphasized that the new scheme will be merely a growth of something that already exists; it will be the wider and better equipped development of educational schemes which have been operating in the Army since the winter of 1940.

Although the Army cannot provide a curriculum so diverse and selective as that of a polytechnic, the War Office has attempted to provide a broad classification of subjects of study within which all soldiers will find something near their requirements and interests. These have been grouped into six wide categories: (1) technology; (2) general science; (3) home, health and hobbies; (4) man and society; (5) commerce and the professions; and (6) arts and crafts.

Under the heading of technology, courses will be organized in electrical and mechanical engineering, building construction, and similar occupations. In general science, men and women will be given the opportunity to study essential scientific principles as applied to manufacture and the professions or the problems of industry and society. The third category is intended to meet many different needs; it is not meant to teach a wage-earning job, but will provide a background knowledge for the soldier who is interested in, say, gardening or poultry-keeping, or the auxiliary who wishes to know more about domestic

subjects. "Man and society" covers sociology in its wider sense while, under "commerce and the professions", courses will be arranged for men and women who wish to make a serious study of business organization or prepare to enter the Civil Service, local government or the professions. The sixth broad field, "arts and crafts", is intended for those who want to familiarize themselves with drawing or painting or musical appreciation. "Men and women who hope to go in for printing or design or architecture or teaching will all find something in this category to provide the first principles of their special need or interest."

The organization of the scheme shows how education in the 'Interim Army' will function in a way which has not previously been possible. Instead of the present system of two compulsory hours—Army Bureau of Current Affairs (A.B.C.A.) and British Way and Purpose (B.W.P.)—there will be six to eight hours a week of education. A.B.C.A. and B.W.P. will be retained as part of these and will be organized on a communal basis as at present, that is, on a platoon or squad or troop basis. For the other four to six hours, men and women will be treated individually and will join with like-minded individuals from any part of their unit to study the subjects they select.

The Army Educational Corps is to be considerably increased in numbers and will be responsible for the general direction of the scheme. But since the programme will be organized on a unit basis, the key men will undoubtedly be the unit education officers, "the 'amateurs', whose duty it will be to publicise the alternatives in the curriculum and to organise the facilities which unit resources can provide". They will be specially trained and equipped with manuals of guidance which should help them over some of their difficulties. The instructors will be selected from unit personnel and will be drawn from officers and other ranks. (The scheme as a whole will apply equally to all ranks.) A start has already been made in training instructors in a wide range of subjects at an Army school specially created for the purpose. Moreover, although the educational scheme for the release period cannot train men for jobs or find jobs for men, unit education officers will be supplied with a steady stream of information which will allow them to give "details of the various trades and professions and the qualifications required for them to those individuals who are in doubt about their careers".

Some of the educational activities will naturally be devoted to the passing of examinations; the Forces Preliminary Examination will apply to the Army in the same way as to the R.A.F. No doubt some unit education officers will be tempted to assess their achievement merely by the number of certificates their units can collect, but they will be strongly urged to keep this 'pot-hunting' in its proper place and concentrate their energies in giving a little to the lot rather than a lot to the few. No scheme of the above magnitude could be attempted without suitable accommodation and a considerable amount of equipment. It is heartening to know that already the premises in which educational work can best be conducted are being earmarked and scheduled for adaptation. Books by the million are also being negotiated for, as are the tools, the raw materials, the films, and other educational accessories.

In assessing the merits of the above scheme, it may be illuminating to recall a little of what happened when a former British Army was sent back to civilian life after a long war. As is well known, a comprehensive educational scheme for the Armistice period after the War of 1914–18 was drawn up by Lord Gorell and his staff. But since there had been no official recognition of education in the Army until September 1918, it can be understood that the scheme for the demobilization period had to be hastily devised and implemented. To the end of the scheme attendance remained voluntary. Further, the accommodation provided for the educational scheme was far from satisfactory in many cases, and often educational activities would have been impossible if the Young Men's Christian Association and the Church Army had not come forward to place their huts at the disposal of the service authorities. Much more unfortunate, the demobilization of men on a profession basis meant that all serving schoolmasters and students were demobilized almost simultaneously early in 1919, leaving the Army without a group of instructors that it could ill afford to lose.

In turning to the scheme proposed for the coming release period, one can see that it starts with many points in its favour. There is now a well-established Army Educational Corps the ranks of which have been considerably increased during the War. The war-time scheme has been in existence for four years already on an official basis, and had been in unofficial operation for some time before that. A measure of compulsion was introduced so far back as 1941. The early problems of accommodation were energetically tackled and in the interim period should present no difficulties incapable of solution. Above all, the way in which demobilization is to take place suggests that instructors and potential instructors will be demobilized in stages rather than as one group, leaving at least some behind who will close their ranks and carry on to the end.

Yet although there are many reasons why the present schemes announced by the Army and the R.A.F. should work, the fact remains that paper schemes, however brilliantly conceived, often fail to go beyond the infant phase. When the schemes are translated into practice, many obstacles will have to be overcome. Men and women who have become used to a life of movement and sometimes excitement will find it difficult to submit to the discipline of the class-room. If this is true of individuals who were previously accustomed to study, it will be ten times more applicable to those for whom regular study was hitherto unknown. The number of competent instructors is not likely to be nearly adequate. These, and other reasons, will present formidable problems. It will, indeed, be interesting to see whether the bolder scheme announced by the R.A.F. achieves more in the long run than the more cautious programme which the Army proposes adopting.

Nevertheless, although the Services are scarcely the ideal places for arranging educational programmes, these schemes should work—and must. The difficulties may be many; frustration and disillusionment will be inevitable. But Service educationists who have developed vast programmes during the War should not find the problem of expanding these schemes during the demobilization period beyond their skill and resource. If they need encouragement, they should be constantly reminded that their individual efforts will together make up one of the greatest contributions to democratic thinking yet attempted.

## PROBLEMS OF DEMOBILIZATION

### The Journey Home

A Report prepared by Mass-Observation for the Advertising Service Guild. ('Change' Wartime Surveys, No. 5.) Pp. 123. (London: John Murray, 1944.) 6*s*.

ALTHOUGH the Government has only just declared its demobilization plans, the question of demobilization has been ably discussed in reports from the political parties as well as in one of the usual admirable broadsheets from Political and Economic Planning. These, however, have been concerned essentially with proposals or principles for demobilization and to some extent this is true of Sir Ronald Davison's somewhat broader survey "Remobilization for Peace" in the "Target for To-morrow" series. Mass Observation, in its fifth major social survey since the War began, makes an attempt to chronicle what people are actually thinking about demobilization and to provide a sample of public opinion on this question for the guidance of those who have to plan "The Journey Home".

The report is admittedly qualitative in nature. Its main statistics are based on 570 interviews, half in London, and half in other parts of the country—in Manchester, Bolton, Newark, Bishop Auckland, and a cluster of Hampshire villages. This material was supplemented by reports from Mass Observation's National Panel of Voluntary Observers, while a series of smaller investigations were made to amplify and clarify trends emerging from the analysis of this material; and although the gross numbers are necessarily small, every effort was made to obtain a justly weighted cross-section.

The first point of interest that emerges from this survey is the soundness of the point made both in the *Planning* broadsheet and in the report of the Conservative Sub-Committee that the Government, having announced the general principles which it proposes to adopt, must see that they are strictly observed. Full publicity and strict observance appear to be even more important than the general details of the scheme, provided it is one which wins the approval and confidence of the members of the armed forces. Mass Observation drives home the point in reference to the points scheme outlined by the Conservative Sub-Committee itself, which, while embodying the type of principle which people appeared to consider a just and fair basis for priority in demobilization, made very little impression on the minds of the civilian population because propaganda was not continuous.

It must, of course, be remembered that sampling opinion by a series of questions in this way has the admitted defect of psychological laboratory tests that the test itself mostly creates an artificial situation which has somehow to be discounted. The questions are liable to start the questioned on an unaccustomed train of thought, at the end of which he finds his opinions are really not at all what he supposed them to be. For all that, a study of the report suggests that the summary does give a composite picture of the hopes and fears of the Englishman or Englishwoman at the time of the inquiry, even if the spontaneity or representative character of particular sets of answers is to be discounted.

The picture, it is true, is largely one that might have been expected. Nevertheless, it throws some light on the conflict in the public mind between ideas of liberty and fairness, between conceptions of democracy and efficiency, and in this respect "The Journey Home" is of interest in relation to the question of other post-war controls than those involved in demobilization. The conclusion that no executive action will be a success unless the hopes, fears, moods and expectations of the masses who will be affected are taken into consideration has a wide bearing on post-war planning. To the extent that tension between expectation, hope and realization leads to a sense of frustration becoming prominent, the possibility of a harmonious solution of demobilization or other social problems recedes.

Clarification of ideas on demobilization is the first step, it is urged by Mass Observation, though "The Journey Home" cannot be regarded as a contribution to that end comparable with Sir Ronald Davison's little book. "People need to know more than how and when they are coming out. They need to know where they are going then. They need to know where everyone is going, what is going to happen to mankind." There is a task, or rather a duty, of exposition or interpretation which is primarily the responsibility of the Government, whether through the Ministry of Information or in some other way, and a popular booklet at a much lower price than "Remobilization for Peace" would be valuable.

But beyond this it might be added that the success of demobilization and of post-war reconstruction depends on people minding enough about the future of mankind to accept responsibility for concrete action themselves. There is nothing in this survey that indicates more clearly the weakness of democracy than the tendency of those interviewed to dissociate themselves from their democratic responsibility by saying 'they' instead of 'we' when they mean the powers that be. The report is a timely reminder of how much yet remains to be done in this direction and how much a democratic system depends on an educated electorate. To the sociologist it is of interest as an example of technique in the analysis of public opinion on any subject, and incidentally raises the fundamental question of what we understand by public opinion. It has, however, a wider appeal to all who are concerned with the prospects and possibilities of post-war planning as indicating not merely some of the dangers and difficulties to be faced, the immensity of the task of education, but also practical problems for each individual, of adapting and fitting his own hopes and aspirations into those of the community as a whole if demobilization is to prove what it is intended to be—the first step towards remobilization for peace, for building up the future of man.

R. BRIGHTMAN.

# DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES

## The Venereal Diseases

A Manual for Practitioners and Students. By Major James Marshall. Pp. xi+348. (London: Macmillan and Co., Ltd., 1944.) 21*s.* net.

IT is both unfortunate and remarkable that the average general practitioner knows so little about venereal disease; unfortunate because it seems not unlikely that he will have to treat much of it in the near future, and remarkable because ignorance of it is all too common. Marshall's "Venereal Diseases" contains just that practical information which the student and the practitioner require, set out clearly and succinctly. No one within the compass of 340 pages can say all there is to be said about venereal disease, but this book does contain the salient facts; almost everything that is excluded is essentially a matter for the expert. Gonorrhœa—the commonest venereal disease—is allotted some ninety-odd pages, into which is crammed a vast amount of information. The anatomy of the urogenital system, without a knowledge of which treatment must be largely empirical, is clearly explained, the importance of pathological examinations in diagnosis rightly stressed, and treatment, especially with sulphonamides, skilfully handled. Case-records indicate how different types of cases should be treated, and any problems not covered by this section should be referred to a specialist. A word of warning concerning the use of sulphonamides in patients previously treated with these drugs, and the possibility of sensitization, might have been included with advantage.

Syphilis is condensed into less than 280 pages—an impossible task if the whole subject is to be covered in detail; for this reason the rarer conditions have been excluded or only touched on briefly, most attention being given to the commoner aspects. The coloured plates, of which there are eight, are for the most part beautifully produced, and represent the nearest approach to real life which the photographer's art can provide. Numerous figures show clearly a variety of morbid conditions, and should prove most helpful to the reader. Stress is, very rightly, laid on the importance of pathological aids to diagnosis; to diagnose early syphilis without these is nothing short of criminal. Treatment of late syphilis must be individualized, and most cases should be referred to experts; that of early syphilis can, however, be more or less stereotyped. That recommended is the 'continuous' with overlapping arsenic and bismuth; many will think the dosage rather heavy in the early phases; but there can be no shadow of doubt that over-treatment is far preferable to under-treatment, and the latter is all too common. The therapist is given the choice of neo-arsphenamine, 'Mapharside' and 'Neohalarsine'; the first-named is the most popular in Great Britain; 'Mapharside' is being used more and more; 'Neohalarsine' is still on trial. The routine bismuth preparation recommended is the aqueous suspension of the metal.

The section on the side effects of arsenicals is particularly good and very important; that of post-arsphenamine jaundice is outstanding, the author being an acknowledged authority on the subject. Arsenical drugs are notoriously dangerous, and everyone who undertakes the treatment of syphilis should know how to handle them. The section on "Other Venereal and Allied Diseases" contains a short account of those conditions likely to be met with in general practice which are venereal or associated with venereal disease. Not everyone realizes the ubiquity of *Trichomonas vaginalis*, nor the fact that scabies is often acquired during sexual intercourse. Warts or condylomata acuminata are often difficult to eradicate, and frequently considerable ingenuity is required to cure a non-specific urethritis; if the directions given are followed, few failures will be recorded.

Practical instructions in irrigation, urethroscopy, dark-ground examination, the giving of intravenous and intramuscular injections, lumbar puncture, fever therapy and prophylaxis, add very considerably to the value of the book, while the appendix on the "Sociology of Venereal Diseases" should be very carefully studied by all who are interested in these diseases as a public health problem; simply to treat the patient with drugs is not the only duty of the practitioner; for every patient with venereal disease who consults a doctor there is always another—often several—who may not even know they have the disease.

It would seem almost churlish to criticize such an excellent book, but criticism may be permissible if it is constructive and perhaps helpful in the preparation of future editions. While the meaning almost everywhere is clear, the English is sometimes loose and the grammar frequently bad; there are plural nouns followed by singular verbs; a vaginal discharge is not a symptom but a sign. "A course of 10 injections is given every other day" will not stand analysis; bi-weekly is a term to be avoided since it can mean twice a week or once in two weeks; instrument is usually a substantive, not a verb; such expressions as "results as good, if not better, than", "Fibrosis which replaces the elastic tissue", "being satisfied that there is no evidence of syphilis . . . a detailed examination of the genitals is made" are not good English and offend the reader.

Some reference to the use of alkalis in combination with the sulphonamides, more use of oil-soluble bismuth, a description of the Dattner lumbar puncture needle, and more information concerning the treatment of non-specific urethritis, would be valuable additions. Nevertheless, there can be no doubt that this book will have a wide circulation, and deservedly so.

# FLOOD CALCULATIONS

## Flood Estimation and Control

By B. D. Richards. Pp. vii+152. (London: Chapman and Hall, Ltd., 1944.) 16*s.* net.

IN this book the author deals with the problem of estimating the maximum flow which may be run off a catchment area during a period of exceptional rainfall. Provision to deal with such maximum flows has to be made in many civil engineering works. In the construction of a reservoir, for example, means must be provided to ensure that when the reservoir is full, all surplus water will be carried off in such a way that the stability of the embankment or dam is in no way affected. Bridges over rivers or streams must have large enough waterways to allow the maximum flood water to flow under the bridge without injuring the structure. Culverts carrying water-courses under roadways or railways must be so

designed that the greatest flow likely to happen may be conveyed without damage to the constructed works. The problem of the engineer is to estimate the probable amount of flood water and to make provision accordingly.

The subject of flood prediction is not new. The author himself points out that it has long been one of the perennial problems of civil engineering. The estimation of such floods is difficult. While, as the author states, floods follow natural laws, the number and complexity of the factors and the interplay between them make precise estimation impossible.

In his foreword, Mr. Binnie regrets that the records of floods which have occurred in the past in the British Isles are limited, and that we are so far behind other countries in taking steps to ensure that such information is available. According to the author, however, a flood of exceptional severity may possibly be met with once only in a hundred years. Complete security can only be obtained, he adds, by ascertaining the maximum possible flood and making due provision accordingly. In connexion with this it may not be out of place to point out that, however meagre the information has been in the past, the civil engineering structures in Britain likely to have been affected by floods seem to have been remarkably well designed to meet such emergencies. The number of reservoir dam disasters in the country in the past century can be counted almost on the digits of one hand. There are bridges over rivers and streams which are centuries old and which have stood the test of time and flood. On the other hand, the number of dam disasters alone, in the United States, run into hundreds. But in America, as on the continents of Europe and Asia, catastrophic floods occur far exceeding anything ever experienced in Great Britain. In whatever country floods occur, the engineer must take into account their possible magnitude, and his designs must be such that they are safe in any circumstances.

The author begins by discussing generally the factors affecting the intensity, duration and discharge of floods. These factors depend upon the rainfall and size and characteristics of the area on which the rain falls. The number of formulæ which have been deduced by previous investigators is impressive. There are no fewer than ten of these given and they do not include all. One of those omitted is the Iszkowski formula so widely accepted in Germany and Austria. The ten given are sufficient, however, to show widely divergent results obtained by the different formulæ when applied to a single rainfall on a given catchment. Most of these do not take into account the shape and contour of the ground. It is the purpose of this book to show how a more accurate estimate of the flood discharge may be made.

Very properly the first point dealt with is rainfall intensity. Rainfall both as a function of time and as a function of area is discussed. Examples of curves as well as actual recordings of intense rainfalls are given, not only for the British Isles but also for Central India, the eastern United States, Southern Rhodesia and Western Australia. Then follows a discussion on the period of concentration intensity and run-off of the flood. There are some interesting graphs showing how coefficients vary on larger and smaller areas when compared with a standard catchment of 25 square miles. The coefficients for flood estimation, taking all the factors—including the size and slope of the catchment—into account, are next dealt with, and then follows the determination of maximum flood discharges by the construction of flood hydrographs. The chapter dealing with the effect of intensity and distribution of the rainfall on the flood hydrograph will be found rather difficult reading by most engineers; but an excellent summary of all that has been written follows. A chapter on flood control as applied to reservoirs deals with open weirs, siphon spillways and under-sluices combined with overflow weirs. The chapter dealing with soil erosion should be of special interest to irrigation engineers Finally, there are some useful examples of flood calculations.

The book will be found of great value to all engineers who have flood problems to deal with. Hitherto the designer of structures which have to withstand the effects of floods has had to rely on empirical formulæ giving widely varying results. He may now, by applying the principles set forth in this volume, arrive at a much more reliable result in determining the maximum flood discharge.

The task of writing such a book as this is obviously an enormous one, and the author is to be commended very strongly on the results which he has achieved.

JOHN BOWMAN.

## SYNTHETIC RUBBER

### Modern Synthetic Rubbers

By Dr. Harry Barron. Second edition, revised and enlarged. Pp. xii+355+20 plates. (London: Chapman and Hall, Ltd., 1943.) 28*s*. net.

IN view of the large amount of material published, especially in the American technical Press, in the last two years on synthetic rubbers, we should expect the second edition of Dr. Barron's book to be a big improvement on the first edition, and such is the case. The general lay-out remains excellent and the contents make interesting reading from cover to cover. It is written in a most readable form and the plates are excellently reproduced. The scope of the second edition is roughly the same as that of the first—economics, chemical and physical background, and technology—but it has been considerably amplified in detail. The first edition has been carefully revised, but a few mistakes such as (p. 29) *GR–N* instead of *GR–M* for Government neoprene have crept into the new edition.

From the point of view of the general reader, there are only two criticisms to offer against this new edition; and they are that the author sets out so obviously to be the champion of synthetic rubber that his views cannot be accepted as unbiased on this important controversy of natural versus synthetic rubber. On p. 177 the statement is made that "the largest and most critical users of rubber, the major American tyre companies, have investigated Buna *S* [it is assumed that Buna *S* is here meant to be *GR–S*] in tyre treads and the general conclusion is in favour of Buna *S* against natural rubber". It is doubtful, in the opinion of the reviewer, whether any tyre manufacturer could be found who would use Buna *S* (or *GR–S*) if alternative supplies of natural rubber were freely available. Other examples of this same attitude could be quoted; for example, on p. 25 the variation (variability) of natural rubber is discussed and the suggestion is made that it does not or *should not* occur in synthetic rubber in the following words: "in fact, the latter [the synthetic

rubber interests] are perhaps more favourably placed since, working from pure materials, they can produce a material of definite properties and characteristics. Synthetic rubbers can virtually be made to specification". Unfortunately, the synthetic rubber interests do not work with pure material—it would be impracticable—and do not produce invariable material; in fact, the variations in synthetic rubbers are as big, if not bigger, than those in natural rubber. In further elaboration of the purity question, the author states on p. 84 that the butadiene for *GR–S* must be 98·5 per cent pure, but it is probable that much *GR–S* has been made from butadiene of as low purity as 95 per cent. When it is kept in view that different processes for butadiene will give different impurities and these impurities may enter into or direct molecular structure in different ways, it is not surprising that the resulting products have been variable to some extent. Experience has shown that chemical control, however detailed, in the shaping of large molecules is a poor substitute for the vital control of Nature.

The second criticism is one which also applied to the first edition, namely, that the author, in spite of his anxiety to see more work carried out on this side of the Atlantic, does not appear to realize how much fundamental work has been carried out in the last few years in Great Britain; for example, on p. 80 no mention is made of the fact that the pioneer work on the production of butadiene from 2·3 butylene glycol diacetate was carried out in Manchester, or on p. 221 that the first copolymers of butadiene and substituted acrylic acids were prepared and evaluated in the same city. Many other British contributions have also been overlooked.

From the point of view of the technical reader, there is a further criticism. The phraseology is sometimes rather unorthodox; for example, on p. 220 there appears the sentence: "While butadiene is the main constituent, there are various synthetic resins, other than styrene and acrylic nitrile which have been successfully developed as copolymer". Synthetic resins are not monomers and styrene and acrylic nitrile are not synthetic resins. The sentence is, in fact, a sort of technical double negative.

In spite of its defects the book is to be recommended to those who wish to acquire a general knowledge of the field of synthetic rubber. W. J. S. NAUNTON.

## ENZYME CHEMISTRY

Chemistry and Methods of Enzymes

By Prof. James B. Sumner and G. Fred Somers. Pp. xi+365. (New York: Academic Press, Inc., 1943.) 5 dollars.

A BOOK on enzymes by the hand of Dr. Sumner might well be expected to present an authoritative review of that phase of enzyme work with which his name is intimately associated, namely, the preparation and properties of crystalline enzymes. In this we are not disappointed. The accounts of the preparations of urease and catalase, of the work of Northrop and Kunitz on the preparation of crystalline trypsin and chymotrypsin, of Anson on crystalline carboxypeptidase, leave little to be desired in an introductory book of this nature. When we turn, however, to the consideration of the larger aspects of enzyme chemistry, Sumner and Somers' book can only be regarded as consisting for the most part of descriptions of the preparations and characteristic properties of a fairly extensive list of enzymes. The distinguishing feature of this compilation is the treatment of each enzyme by short statements under a number of headings such as history, occurrence, action, specificity, etc. The statements tend to be very brief, with a consequent curtailment of any critical discussion of the properties of enzymes and of recent work bearing upon their mechanism of action. The authors state, however, that they have attempted to give the research worker and advanced student a general survey of enzyme chemistry without presenting too much detail on any subject, and in this objective they may be said to have succeeded—perhaps only too well.

The book commences with a chapter on the general properties of enzymes. This deals mostly with the physical chemistry of enzymes. The treatment, in common with that of the rest of the book, is sketchy and terse, lacking the details and explanatory data necessary to make the somewhat complicated subject of enzyme kinetics clearly intelligible to the student. The chapter deals briefly with most matters proper to a physicochemical description of enzymes and includes short statements concerning activators, protective substances, poisons, coenzymes and anti-enzymes.

The remaining seventeen chapters of the book are concerned with a fairly comprehensive survey of enzyme systems. These are classified into the hydrolytic group comprising the esterases, carbohydrases, phosphorylases, nucleases, amidases, and proteolytic enzymes; the oxidizing group comprising those enzymes possessing iron-containing constituents, and those depending for their activities on the presence of copper, the various dehydrogenases and flavin-containing enzymes, and a batch of oxidizing enzymes which apparently defy adequate classification; and finally the desmolases.

The final part of the book consists of two chapters, the first of which is devoted to a brief description of hydrases and mutases, and the second to a description of some mechanisms involved in carbohydrate metabolism as illustrative of the manner in which enzyme reactions in the living cell are brought together.

Omissions of greater or lesser importance must obviously be characteristic of a book which aims at curtailment of detail. Sumner and Somers' book suffers from the omission of many facts concerning enzyme chemistry of equal interest to those actually presented. Thus, to give a few examples, nothing is said of the ability of lactic dehydrogenase to reduce alloxan in the absence of a coenzyme, a fact pertinent to any discussion of the mechanism of action of the coenzyme-linked dehydrogenases. Nothing is said of the inhibitive action of oxalacetic acid on the activity of succinic dehydrogenase and of the importance of thiol groupings in the make-up of this enzyme. There is but little mention of the reversible poisoning of enzymes by dyestuffs, of the effects of narcotics on respiratory enzyme systems, or of the general principles of competitive inhibition of enzymes so important to-day in the interpretation of many facts of therapeutic and pharmacological significance.

In spite of these shortcomings, Sumner and Somers' book will undoubtedly prove to be of much interest to the student of enzyme chemistry, and it is a welcome addition to the steadily increasing number of text-books on the subject. J. H. QUASTEL.

# COLONIES OF *PENICILLIUM NOTATUM* AND OTHER MOULDS AS MODELS FOR THE STUDY OF POPULATION GENETICS

By Dr. G. PONTECORVO
Department of Zoology,
AND
Dr. A. R. GEMMELL
Department of Botany, University of Glasgow

EXPOSURE of mould colonies to X-rays has long been known to give rise to 'sectorial' mutants. Mutant 'sectors', of course, also arise 'spontaneously' in Fungi as well as in Bacteria. The frequency varies between strains, but is always much smaller than the maximum obtainable by irradiation. *Penicillium notatum* is no exception, as we have obtained mutant 'sectors' in abundance following irradiation, and occasionally without irradiation. All 'sectors' isolated gave rise to mutant strains, differing from the original in morphological or metabolic properties.

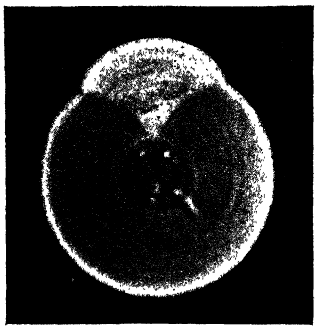

Fig. 1. 'SPONTANEOUS SECTOR' OF *Penicillium notatum.*

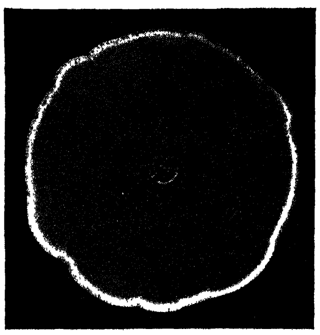

Fig. 2. IRRADIATED COLONY SHOWING MUTANT 'SECTORS' OF DIFFERENT SHAPES.

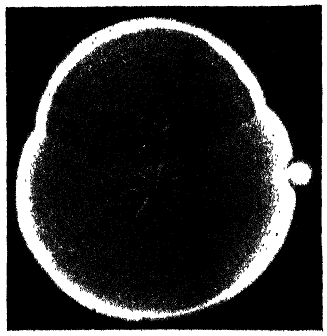

Fig. 3. TWO SEPARATE COLONIES WITH DIFFERENT GROWTH-RATES MEET AND COMPETE FOR THE SAME TERRITORY.

The analogy between 'sectoring' in Fungi and somatic mutation, or segregation, in Metazoa and Metaphyta is evident. But the two-dimensional type of growth of mould colonies makes them an unparalleled material for following the fate of a single mutated cell in a growing population of cells. Natural selection and chance can be seen here at work, under measurable conditions, and leave, as it were, a graphical record of their effects.

It is surprising indeed that so little attention has been paid to the strikingly regular shapes of sectors, both 'spontaneous' (Fig. 1) and induced (Fig. 2), and to the significance of these shapes. Even though the term 'sector' is a geometrical misnomer, since the majority have curved borders or open out at too great an angle, most 'sectors' lend themselves to description in very simple geometrical terms. They may be classified into three elementary types and combinations of them. Fig. 3, *a, b, c* show diagrammatically these three simple types, and Fig. 3, *d*, one of the complex types, a combination of *c* and *a*. Whereas 'sectors' induced by irradiation may show any one of the three elementary shapes and of their possible combinations, 'spontaneous sectors' in Fungi and Bacteria are almost exclusively of type *a*. It will be noticed (Fig. 3) that X-ray induced sectors have their origin where the edge of the colony was at the time of irradiation. This is simply because the increase in diameter of a colony takes place by multiplication of cells in or near the hyphal tips that form its edge. A nucleus has, thus, a chance to give rise to a patch of mutated mycelium only if it was situated on the growing fringe of the colony at the moment it underwent mutation. But it will also be noticed that whereas 'sectors' of type *a* taper towards the irradiated edge from which they originate, types *b* and *c* originate in a sort of blunt apex. We shall see why later.

Before discussing the geometry of 'sectors', let us consider the mode of growth of a mould colony under certain conditions (hard agar and others) which are essential for obtaining regular shapes. Under these conditions, growth of colonies is, as a first approximation, two-dimensional. A hyphal tip or a germinating spore free from competition branches in all directions in a plane so rapidly that it soon forms a circular microcolony; from this moment the colony grows as a circle, expanding in diameter at a uniform rate so long as there is further medium to occupy. The hyphæ elongate radially, with little intertwining, and branch to fill the increasing space available. The circular expansion of a colony made up of homogeneous mycelium is the resultant of the potentially circular expansion of each one of its myriads of hyphal tips, limited by the fact that the territory occupied by one hypha cannot be occupied by another. Hence (1) if a hyphal tip in a large colony were set free from the competition of its neighbours, it would soon produce a roughly semi-circular microcolony bulging out from, and with centre upon, the edge of the larger colony; (2) competition between hyphæ is extremely severe, and consequently natural selection has plenty of scope for operating.

Let us now suppose that in such a homogeneous colony a hyphal tip suddenly changes its growth-rate. If the new growth-rate is lower, usually the mutated hypha will soon be surrounded by branches of its neighbours and prevented from further growth. No trace of the event will be visible. If the new growth-rate is higher, on the other hand, usually the result will be a 'sector' of type *a* (Fig. 3, *a*), the boundaries of which are parts of equiangular spirals, with characteristics depending on the ratio of the two growth-rates and the diameter of the mother colony when the changed system arises. A verification of this geometrical explanation can be made by deliberately imitating natural sectors. If a small inoculum is made with a suspension of spores of two strains having different growth-rates, and the spores of slower growth form a big majority, the results are indistinguishable from 'sectors' of type *a*

(Fig. 4). It seems that a mutation endowing a hyphal tip with a higher growth-rate is all that is needed to explain the shape of 'spontaneous' and X-ray induced 'sectors' of this type.

The shape of 'sectors' of type *b* seems, at first, rather mysterious. The straight sides proclaim them to have a growth-rate equal to that of the mother colony. But with an equal growth-rate a hyphal tip should not be able to produce a 'sector' other than one with vertex at the centre. 'Sectors' of this kind do occur after irradiation, but not frequently. Most type *b* 'sectors' have vertex away from the centre. Again, the imitation of 'sectors' by mixed inocula has given a clue to a possible mechanism. If a small inoculum is made with a thick suspension of spores of two strains with equal growth-rates, the result is a colony made up of nearly radial sectors of one strain alternating with similar sectors of the other, a sort of rising sun figure (Fig. 5). If, however, the inoculum is large, irregular in shape and contains few spores, some of the sectors open out at great angles. Obviously some initial positional advantage plays a part. The next step is to control this positional advantage by starting two colonies, one of each strain, at different times and near each other (Fig. 6). The results are as those given by the intersection of two systems of concentric circles, expanding at the same rate, but differing in diameter when they first meet. The intersections are hyperbolæ and the angle between the asymptotes depends only on the ratio of the two diameters when the systems first meet (Fig. 3, *e*). The smaller the diameter of the small colony (or system) in relation to that of the larger one, the smaller becomes this angle and the more nearly do the sides of the resulting 'sector' coincide with the asymptotes and look like straight lines forming a blunt vertex. To explain 'sectors' of type *b*, to which many of those produced by irradiation belong, we have thus only to assume that the mutated hypha either had, immediately after irradiation, a positional advantage over neighbouring hyphæ, or that it enjoyed for a short time a much higher growth-rate. Plausible mechanisms of either type are easily imagined. For example, irradiation may kill a high proportion of hyphal tips and the surviving ones have a greater *Lebensraum*. Alternatively, differences in metabolism between mutated and non-mutated hyphæ may give one of the former a temporary advantage depending on conditions of the medium temporarily altered by irradiation.

'Sectors' of type *c* are nothing more than a modification of the preceding case; that is, the mutant has an initial temporary advantage, but a growth-rate lower than that of the mother colony. The experimental imitation of 'sectors' of this type needs no comment (Fig. 7).

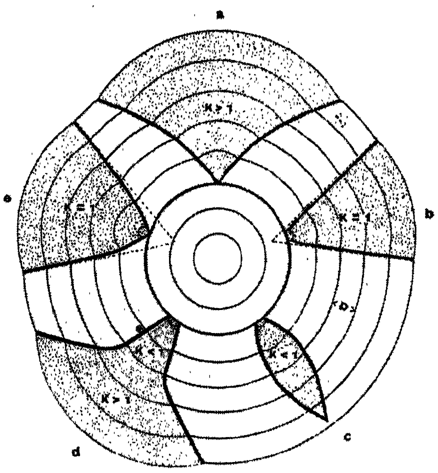

Fig. 3. GEOMETRY OF 'SECTORS': *a*, *b*, *c*, THE THREE SIMPLE TYPES, *d*, ONE OF THE COMPLEX TYPES, *e*, 'SECTOR' OF TYPE *b* IMITATED BY STARTING TWO COLONIES WITH EQUAL GROWTH-RATES AT DIFFERENT TIMES. HEAVY CIRCLE INDICATES EDGE OF COLONY WHEN IRRADIATED. *K*, RATIO OF GROWTH-RATES OF SECTOR AND COLONY; *D*, INCREASE IN RADIUS PER UNIT TIME.

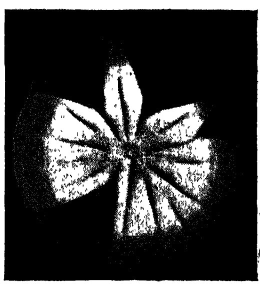
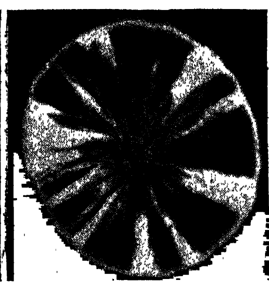
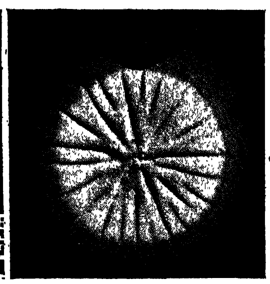
The types of 'sectors' so far discussed are those in which mother colony and mutant have growth-rates bearing a fixed ratio to each other over a long period. A number of sectors with shapes interpretable as combinations of those so far described, however, are obviously not of this type. The ratio changes as the colony grows old. This may be due to a special growth habit of the mutant, that is, something detectable even if the mutant is grown by itself, or it may be due to an interaction between mutant and mother colony. Among the mutants we have isolated both types are represented. A simple example of non-reciprocal interaction is that of a mutant which grows more slowly than the normal strain on acid medium and more quickly on alkaline medium. As the *p*H of the medium changes (from acid to alkaline) with the growth of a colony, so also does the intersection curve between normal and mutant colonies grown side by side; its final form depends on the time of inoculation of the mutant after the establishment of the normal colony. If very soon (acid medium), the mutant will form a type *c* 'sector'; if somewhat later (acid medium changing to alkaline), the mutant will form a type *d* 'sector'; if still later, the mutant will expand at the expense of the normal.

Cases of reciprocal interaction, namely, antagonism or collaboration, between two or more strains are identifiable and analysable by some such methods. Another problem, in addition, can be investigated along these lines: that of changes in the medium,







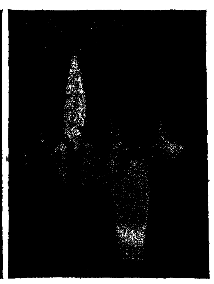


Fig. 4. Fig. 5. Fig. 6. Fig. 7.

Figs. 4–7. IMITATION OF VARIOUS TYPES OF 'SECTORS' BY INOCULA OF TWO STRAINS WITH EQUAL (FIGS. 5, 6) AND DIFFERENT (FIGS. 4, 7) GROWTH-RATES. FIG. 5 GIVES A GRAPHIC MODEL OF THE SEWALL WRIGHT EFFECT.

produced by the growth of a colony, which put a premium on mutants more fit than the mother colony for growth in the changed medium. This problem is that of formation of secondary colonies, which is familiar to bacteriologists.

Between the occurrence of a 'visible' mutation and the establishment of an actually visible patch of mutated mycelium there is a long way to go. In the initial stages, before the mutant has succeeded in securing a 'bridgehead', its survival or extinction is almost entirely a matter of chance. Once the bridgehead is secured, the systematic advantage or disadvantage of the mutant with respect to the parental strain determines the characteristics of the surfaces occupied by each, and therefore the ultimate fate of the mutant. Figs. 1, 4, 8 are examples of the simplest case, that of two strains one of which, with a higher growth-rate than the other, will ultimately supplant it. With certain obvious restrictions, these are models of the spread of a favourable gene in a population under the stress of natural selection alone. In Fig. 1 the mutant starts as a single individual in a large population; in Fig. 4 the mutant starts as 10 per cent of the initial population; in Fig. 8 two separate populations with different growth-rates start at the same time and compete for the same territory: the boundary between them is a circle.

It is, however, as models of the accidental multiplication or elimination of genes, and its dependence on the size of the population, that mutants of moulds can be most useful. Mixed colonies of strains with equal growth-rates are especially instructive, since in them the effect of natural selection between strains is nil, and that of chance alone stands out. A colony of this type, begun with great numbers of spores of each of two strains, shows (Fig. 5) in its early stages an apparently thorough mixture of both. Later on, the colony becomes made up of clearly distinct sectors each of either one or the other strain. As, with appropriate magnification, the early apparent mixture is seen to result from an alternation of very thin radial strips of each strain, the difference between earlier and later structure is simply a substitution of fewer sectors of great width for an initial very large number of sectors of very small width. Clearly a process of sorting out takes place: sectors which are too small in width either increase in width or disappear. The result is that any small apparently mixed arc in the young colony gives rise, after sufficient growth, to an arc in which one strain only is established to the exclusion of the other.

Here is an evident analogy with the Sewall Wright effect of the small size of populations upon the accidental fixation or extinction of genes. In the case of sexually reproducing species, the effect is due to the sampling nature of the reproductive process: accidental fluctuations in the frequency of a gene may, in a small population, reach the irreversible alternatives of either fixation or loss. In mould colonies a similar sampling operates. A hyphal tip in a colony of radius $r$ gives rise, *on the average*, to $r'/r$ hyphal tips when the colony has grown to radius $r'$. Accidents of growth, however, allow for fluctuations around this average: one hyphal tip will contribute more to the next 'generation', and another one less and leave no 'progeny'. In a small arc, with a small number of hyphal tips of two strains alternating, these fluctuations will be reversible and preserve the mixed constitution of the arc, so long as they do not happen to reach the irreversible state of all hyphæ being of one or the other strain. This will ultimately bring about the segregation of the two strains into 'sectors' of substantial size. To grasp fully the analogy between the Sewall Wright effect in sexually reproducing organisms and our example, one has to substitute a hyphal tip for a gene, and a small arc of the colony for a small population.

There are several possible ways of measuring the intensity of the sampling effects in moulds: unlike the sampling effect of sexual reproduction, its variance may be expected to depend on external conditions.

In conclusion, the remarkable diagrams that mould colonies may be made to produce offer a range of opportunities for the experimental approach to problems as apparently unrelated as morphogenesis and genetics of populations.

We wish to thank Miss A. H. Waddell for advice on the mathematical side, and Dr. W. M'Farlane, who carried out the irradiations at the Western Infirmary, Glasgow, for his most helpful contribution to our discussions. A research grant from the Carnegie Trust for the Universities of Scotland has covered part of the cost of materials.

# FOUNDATIONS OF ELECTRICAL MEASUREMENT*

By Dr. L. HARTSHORN
National Physical Laboratory

THE last two or three years have seen the publication of a surprising number of papers on the fundamental magnitudes of classical physics. Even more surprising is the divergence of opinion expressed on such well-worn themes as the precise significance of the magnitudes of everyday electricity and magnetism. Well-known expounders of these subjects at our universities have found one another unintelligible, and practising engineers and physicists have frequently been heard to ask if these concepts are really as doubtful as all that after half a century of experience and discussion.

There seems to be fairly general agreement that the working concepts should be defined by reference to the processes by means of which they are measured, but there is no sort of agreement as to what these processes are. It appears that there are many possible processes for each quantity and no agreement as to their relative status. One of the troubles is that the processes described are usually idealized. They have been described as 'theoretical experiments'. It is agreed that they have not actually been performed, but it is asserted that they could be performed in principle; for example, you take two point charges and measure certain distances and forces and so on, operations which appear to the experimentalist of to-day as practically impossible, and in the results of which he would have no confidence whatever.

An outstanding fact, and one which the experimentalist finds very reassuring, is that all the doubt and discussion surrounding these theoretical experiments seem to produce no repercussions on his own real experiments. His values are usually accepted without argument, understood and acted upon with useful results. He can only conclude that these theoretical operations about which there is so much argument cannot really be the basis of the laboratory work, which remains unaffected. The extent of our

* Based on a lecture to the Measurements Section of the Institution of Electrical Engineers delivered on May 19.

agreement in practical matters shows that we must be working on some common basis. It is curious that it is so difficult to express it in terms on which we are all agreed.

Dr. Norman Campbell alone in recent years seems to have felt the necessity of maintaining a close and direct connexion between the principles and experimental laws which he enunciates as the basis of our measurements, and the methods that we actually employ in our everyday work. His work has, however, been strangely neglected in the recent discussions, and unfortunately, as he himself has pointed out, the matter is too complicated to be adequately covered by a few simple statements of the kind frequently offered. These are rightly used in introductory text-books, where it is expedient to conceal complexities until the more prominent ideas have been grasped, but when trying to find our basis the complexities must be faced. In these circumstances it would obviously be impossible to give here a precise statement of the position, but it may be of interest to indicate in broad outline some of its main features.

Measurement is essentially the derivation of numbers that are capable of representing physical properties in their relations to one another; and just as the various physical properties are defined by reference to the process adopted for their measurement, the numbers used in experimental physics are the symbols representing the results of the familiar physical or experimental operation of counting. The characteristic properties of numbers are the laws of addition, from which the other mathematical operations employed are derived, repeated addition leading to multiplication, the reverse operations providing subtraction and division, and so on. Thus the first condition to be satisfied in order that measurement may become possible is that some physical properties must obey laws that are analogous to the laws of addition for numbers. Another requirement is that operations must be devised that will enable us to judge of two objects, whether one is greater than, equal to, or less than, the other, in respect of some particular property. In short, judgments of equality and laws of physical addition form the basis of the whole problem.

It is generally agreed that in all our practical work we shall take length, mass and time as the primary properties, and probably everyone would agree with the statement that these quantities are all additive, though it is far from easy to say exactly what this statement means. Attempts to do so are apt to be tedious, but it is of interest to note that the measurement of these quantities depends only on the operations and principles mentioned above.

Length we define by reference to rigid rods. Judgments of equality are made by putting rods side by side and judging the alignment of fiducial marks or the coincidence of the planes of end-faces. Physical addition is performed with such rods by placing them end to end and in line. What justifies us in calling such a process addition ? Briefly, it has characteristics similar to those laid down in the laws of addition, commutative, associative and distributive, the essential ones being as follows. First, whenever we perform the operation an increase of length is brought about, as can be established by our ability to judge equality, etc. Secondly, if we apply the process to a number of such rods, the length of the combination is always the same, however the various operations are performed and in whatever order they are carried out.

It is easy to see that any property for which such a law of addition can be established becomes measurable if we can devise means for producing objects that are judged equal. We can by adding together many such objects produce a succession of systems of steadily increasing magnitude, which constitute a standard scale for that property. Any object to be measured is compared with the systems of the standard scale, and when the two are judged to be equal, we count the number of original equal objects in the composite system. The familiar devices for reducing the labour of counting, and for increasing the precision of the process by including subdivisions in the standard scale, depend only on the same laws of addition.

The direct application of these laws to measurements of length of the highest precision is well illustrated by the use of sets of slip gauges. The physical addition of these gauges by their wringing surfaces is daily giving results consistent to one millionth of an inch. The application to mass is too obvious to need description, but time and frequency differ somewhat from the other primary magnitudes. In practical work we are solely concerned with periods of time, a concept based on recurrent phenomena. In rotating and vibrating systems, we recognize certain features which recur regularly. These recognizable features are regarded as defining instants separated by periods of time, and we can judge instinctively whether two such instants are simultaneous or whether one is 'before' or 'after' another. We choose some definite system as a standard and define its characteristic periods as equal intervals of time. Then the time between any two instants is, by definition, to be measured by counting the number of recurrences of the standard, after the first instant and before or simultaneous with the second. Clocks are standard periodic systems attached to mechanical counting devices or adding machines.

Frequency, which is perhaps more important than time in electrical work, is merely another aspect of the same phenomena: it is just the number of recurrences of the system in each standard period. A clock without its calculating machine is a frequency standard. It is well known to all wireless engineers that laws for the physical addition, subtraction, multiplication and division of frequency of certain periodic electrical systems have been experimentally established and that actual measurements of frequency are often made with the highest precision in virtue of these laws. It is a fortunate fact of Nature that these laws are consistent with our notion of time, which is additive by definition.

Angle also should be regarded as one of our primary properties. It is essentially a property denoting difference or change of direction, that is to say, a property characteristic of the faces of rigid bodies like crystals, or alternatively, one characteristic of the operation of rotation or of rotating systems. There is a common delusion that the measurement of angle is based on that of length, but both 'static' angles and angles of rotation are in practice measured fundamentally using only laws of addition, and there is close correspondence between the two. Anyone who has calibrated a divided circle will know that measurements of length play no essential part in the process, but that the essence of the matter is the continued addition of a number ($n$) of equal rotations until exactly one complete turn has been made. Each of the equal rotations then bears the relation $1/n$ to one complete revolution. Obviously angles

of this kind are also measured whenever we count revolutions.

A most interesting illustration of the fact that angle of the other kind is measured fundamentally, and of its relation to rotation, is provided by a new system of angle gauges recently developed at the National Physical Laboratory by Dr. G. A. Tomlinson. They consist of pieces of hardened steel with plane faces $3\frac{1}{2}$ in. $\times$ $\frac{5}{8}$ in., inclined together at various angles and so truly plane that they can be wrung together to form combinations like length gauges. This is the process of addition. Equality of angles could be tested by the parallelism of corresponding faces, and thus starting with an arbitrary unit angle, standards of 1, 2, 2, 5, etc., or 1, 2, 4, 8, etc., could be established and any desired angle produced by addition. Tomlinson has, however, greatly simplified the practical problem by making use of the fact that if two equal standards are added with their directions reversed, their external faces are parallel, that is, their sum is zero: in other words, in this case physical subtraction as well as physical addition is possible, and therefore with a given number of gauges more combinations are possible. Tomlinson uses only twelve gauges of angles 3″, 9″, 27″, 1′, 3′, 9′, 27′, and 1°, 3°, 9°, 27°, 41°, and with these he can quickly produce any angle between 0° and 81° to within $1\frac{1}{2}$″ of its nominal value, some 97,000 possible values.

Measurements of angles of rotation can obviously be made with these gauges in conjunction with an auto-collimating microscope. The appropriate gauge is placed on the rotating member with one face perpendicular to the axis of collimation. The other face is, of course, not visible through the gauge, but it becomes available for inspection by wringing any plane reflecting surface on to it and arranging this surface so that it projects beyond the edge of the gauge and is thus exposed to the collimator. The rotating member is now turned until the second face becomes perpendicular to the collimator axis, as is shown by a zero reading in the eyepiece. The angle of rotation is then equal to that of the gauge. The gauges require no accurate centring, and provide a relatively simple method of measuring angle with the highest precision. Of the first four sets of gauges constructed at the National Physical Laboratory the average error was only 0·2″, and only three gauges out of forty-eight had errors so large as 0·5″.

Measurements of this kind, based solely on laws of physical addition and judgments of equality, are called by Norman Campbell fundamental or independent measurements. Not only are they employed for the most precise measurements of the primary mechanical properties; they are also employed for the most precise measurements of electrical properties. In the National Physical Laboratory, for example, they are employed for the basic measurements of resistance, capacitance and mutual inductance, and the laws of addition for these properties are the ones on which our electrical measurements primarily depend. Resistance is additive for conductors connected in series; capacitance for condensers connected in parallel; and mutual inductance for pairs of coils each consisting of a common primary coil and a secondary coil, when the secondary coils are connected in series. Standard scales for these quantities analogous to the scale of length are built up by the successive addition of resistors, condensers and inductors that are judged to be equal, the various bridges and balancing devices employed in making these judgments being detectors rather than measuring instruments, and serving only to amplify our senses.

Other electrical quantities which are additive are conductance, additive for conductors connected in parallel; electromotive force, additive for cells in series; and current, additive in circuits in parallel connexion. These quantities can all be measured fundamentally with high precision over a limited range. For measurements over a wider range other processes of measurement are used. For conductance we usually base our measurements on the law connecting it with resistance, which it may be noted is very similar to that connecting frequency and time.

Fundamental measurement is obviously severely limited in its scope, since each property is measured independently of any knowledge of any other property. But it is the relations between different properties that give to physical science its great scope, and modern experimental technique consists largely of measurements based on the numerical laws expressing these relations. It is important, however, to recognize that these numerical laws are entirely dependent on the laws of fundamental measurement that have previously been established for certain of the properties. It is only possible here to consider the first two or three in the sequence of derived laws which forms the basis of our experimental work. The great bulk of the electrical apparatus used in Great Britain is calibrated by instrument makers by reference to standards calibrated at the National Physical Laboratory, and therefore measurements made with this apparatus must be based on the laws adopted at the National Physical Laboratory for standardizing purposes.

The first of these laws is that connecting mutual inductance $M$ and geometrical properties. It can be written

$$M = \mu_0 N,$$

where $N$ denotes Neumann's integral $\iint \frac{ds_1\, ds_2 \cos \varepsilon}{r}$.

We have seen that for certain systems $M$ can be measured fundamentally. For many such systems $N$ can be expressed in terms of lengths and angles, which can also be measured fundamentally. It therefore becomes possible to establish with very high precision the law that for all mutual inductors constructed of non-magnetic material, $M$ and $N$ are proportional to one another, the proportionality constant $\mu_0$ depending only on the units adopted for $M$ and $N$ respectively. It can also be established that for inductors made of magnetic material the law becomes $M = \mu N$, where $\mu$ is constant for any one material, but varies with change of material. This law therefore provides a process for the measurement of the property $\mu$ characteristic of magnetic materials. It is the law defining magnetic permeability, and most of the usual methods of measuring permeability are directly based on it. The constant $\mu_0$ must now be interpreted as the permeability of all non-magnetic materials. We can regard it as having the dimensions 1 in inductance, and $-1$ in length, if we find the practice useful, and it is convenient to write its value as $10^{-9}$ henry per cm. The unit of inductance, the henry, has of course been fixed by assigning this value to $\mu_0$.

Our next law is that of the electrodynamometer, which forms the working basis of most of our measurements of current. It can be written

$$F = a\, I^2 \frac{dM}{dz},$$

where $F$ denotes the mechanical force between two coils when each carries the same current $I$, $M$ denotes the mutual inductance between the coils, and the $z$-axis is the direction of the force. This law has been established with the highest precision for the special case of the current balance built of non-magnetic material, the force $F$ being determined by weighing, in terms of mass, and the quantity $\frac{dM}{dz}$ by application of the law of mutual inductance in terms of the geometrical property $\frac{dN}{dz}$. $I$ can be measured fundamentally over a limited range, and thus the dynamometer law is established by means of the current balance in the form

$$mg = a\, I^2 \mu_0 \frac{dN}{dz}.$$

The proportionality constant $a$, unlike $\mu_0$ in the previous law, appears to be characteristic of no important property. We therefore choose our unit of $I$ so that $a$ takes the value of unity and disappears from our working equation, which becomes

$$F = I^2 \frac{dM}{dz}.$$

Next in the sequence is Ohm's Law, the law of the potentiometer, which can be established in the form

$$E = b\, I.R,$$

since both $E$ and $R$ can be measured fundamentally, while $I$ can be measured both fundamentally and by means of the dynamometer law. The constant $b$ appears to be characteristic of no important property and is therefore suppressed by a suitable choice of units for $E$ and $R$.

It is impossible to pursue the subject further here, but the examples given are sufficient to show the kinds of law that form our real foundations at the present time. These foundations change to some extent with changing technique. The basic laws are those of the instruments and operations which have enabled us to correlate our experiences with the highest precision, and have therefore been used in establishing our working standards. At the present time, alternating currents are employed for precision electrical work to an increasing extent, and therefore some of the laws concerning alternating currents are of basic importance. Note that the electrodynamometer law provides us with a means of measuring alternating current as well as direct current, and then by means of the electrostatic voltmeter we can extend Ohm's Law to certain classes of conductors, namely, resistors. Thus we can define and measure alternating potential difference. Faraday's Law of Induction can then be established in the form in which it states the relation between the alternating potential difference at the secondary terminals of a mutual inductor $M$ of which the primary carries a current $I$. Adopting the usual vector notation, we establish the law

$$E = kM\omega I,$$

and then choose the unit of $E$ so that $k = 1$. The constant $b$ which appeared in Ohm's Law is then suppressed by a suitable choice of the unit of resistance.

It is unfortunate that this system of laws, upon which our experimental work is based, does not readily link up to form a simple logical development of the theory of the subject; but once we have recognized the great difference between the basic experimental laws and the theoretical relations which have been devised as the simplest easily workable system consistent with these laws, we are prepared to find differences of opinion as to which theoretical scheme can be used with the least risk of confusion.

# PSYCHOLOGICAL ASPECTS OF MORAL PROGRESS

A WIDESPREAD readiness to re-examine human values makes it particularly appropriate at the present time to ask whether recent scientific work can add to our understanding of moral advance. This was the question taken up in a discussion on "Psychological Aspects of Moral and Social Progress" at a meeting of the British Psychological Society on September 23, in which the chief speakers were Prof. J. C. Flugel, Prof. Karl Mannheim and Dr. R. H. Thouless.

In opening the discussion, Prof. Flugel suggested that, as a first approximation, we may identify eight mental tendencies exhibited in what we regard as moral progress. Once recognized, they can be illustrated in three fields of comparison: they differentiate the mind of the infant and child from the more mature mind, the abnormal (pathological) mind from the healthy mind, and the primitive from the civilized culture. These eight tendencies may be briefly stated.

(1) There is a trend away from ego-centricity and towards sociality, an increasing readiness to subordinate one's own immediate requirements to the needs of one's fellows, and to find satisfaction in the well-being of groups ever more broadly conceived, so that what starts as a concern for a few family associates may develop into loyalty to a nation, a church, or the whole human race. Among the psychological mechanisms involved in this process, an important part is played by vicarious satisfaction; our interest goes out to people very different from ourselves because they represent some of what William James called the 'potential selves' which we all give up in becoming our own one self.

(2) Progress towards greater consciousness, away from the control of conduct and feeling by unconscious urges, also appears in the advance towards individual maturity and civilized social organization. Progress along this line is pre-eminently the aim of psycho-analysis. At the same time, it must be recognized that, conscious scrutiny having thoroughly performed its task, much behaviour has to be relegated to the habitual and the automatic. Individual conscious life is supported by a mass of habits, reflexes, and other non-conscious determining tendencies. In social life, traditions and conventions have a similar role. Their value lies in the economy they effect, their danger in that they may grow antiquated and ill-adapted; but they must always be necessary in mental and social organization, simply because the span of consciousness at any one time is strictly limited.

(3) The trend towards realistic thinking, away from dreaming and 'wishful thinking' in individual life, and away from magic in social life, is a third mark of advance. Science, Freud has suggested, is essen-

tially an endeavour to think according to the 'reality principle'.

(4) Social and individual progress shows a gradual replacement of aggression by tolerance. Primitive and infantile mortality is marked by a sweeping aggressiveness which gives place in later development, to finer discriminations and broader tolerance. The mature mind can better tolerate unwelcome stimuli, including new points of view, and has less need to react in aggressive defence of things as they are. In one respect this appears as the toleration of criticism which is vital to science; in another as that capacity for 'collaboration in opposition' which Madariaga has noted particularly in the British national character.

(5) A trend is to be seen in individual and social advance towards spontaneity in doing what is regarded as right, in contrast to the more primitive reliance on strong prohibitions against 'wrong' impulses after they have arisen. In the child's development, the external prohibitions are replaced by the internal control of the super-ego, and with increasing maturity the conflict grows less between the super-ego and the impulses it controls. One aim of psycho-analysis is to replace the crude inhibitory power of the super-ego by the ego's more delicate discrimination. So, too, right behaviour among primitive groups depends more on taboos and the avoidance of sins, but in civilized societies more upon the sublimation of impulses into permissible channels.

(6) A progressively greater freedom from irrational anxieties is seen in the child's development and in the advance from primitive to civilized societies, superstitions and phobias being shed, bogies of all kinds less and less remembered. In psycho-analysis the patient's progress exemplifies the same trend.

(7) As development proceeds, the individual shows increasing self-responsibility. In controlling his behaviour he judges with greater autonomy, and is less at the mercy of the ready-made morality of the group or the super-ego. The same tendency is seen socially in the advance from generalized taboo to reliance on individual conscience; and, politically, towards democracy instead of submission to a dictator.

(8) The eighth developmental trend shows moral judgments increasingly penetrated by intellectual understanding. The cognitive approach to what we disapprove of begins to displace the mainly affective and conative procedures of condemnation and attack. In reply to discussion on this point, Prof. Flugel made it clear that a moral judgment must always remain, and action must be taken against what we condemn; but with increased maturity the means adopted will be chosen in the light of much fuller intellectual understanding. The handling of delinquents illustrates the point: the modern effort to investigate, to view separately the sin and the sinner, is an advance beyond the simple condemnation and punishment which, considering that they have been practised for some millennia, have achieved relatively little.

Prof. Flugel suggested these eight tendencies only as a first approximation, and he later inclined to agree with Dr. Thouless that a ninth should be added—the tendency towards greater voluntary control of action, the passage from uncontrolled to controlled behaviour. While adding this ninth tendency, however, Dr. Thouless was emphatic that he could not regard such tendencies as aspects of 'progress'. He viewed them as a description in psychological terms of the criteria by which we distinguish between the better and the worse in conduct. That the better does in fact come later in the life-history of the individual and the social group is a separate question, to be decided only by an examination of the facts of child psychology and of anthropology. The term 'moral progress' implies an answer to this question, which may or may not be true. He doubted, for example, whether the tendency towards sociality and away from ego-centricity is greater in civilized than in primitive groups.

Prof. Mannheim, reading the first paper in comment upon Prof. Flugel's thesis, had already given critical attention to the concept of 'progress'. Speaking as a sociologist—and welcoming a discussion that brought both psychology and his own science to bear on the problem—he pointed out that the notion of progress grew up in the nineteenth century, an era of industrialization and economic expansion. Impressed by the seemingly endless possibilities of material advance, thinkers of the time carried over the same optimistic attitude into their view of the human mind. But this confidence in social and moral advance as an inherent feature of the historical process has been deeply shaken by the political and international events of the twentieth century.

In Prof. Mannheim's view, society shows no inevitable cultural development through recognizable stages. Such a phenomenon as Germany's return to the tribal mind and over-socialization is not to be termed a 'regression', for the trend in the opposite direction is not a normal or natural process. To suppose that it should be, is to blind ourselves to the more important moulding of behaviour by environmental conditions. For a detailed understanding of a group at any period our chief need is, not to know what point it has reached on a linear scale of progress, but to relate its current mental attitudes to its concrete environment, social and technical.

As an example, Prof. Mannheim pointed out that an industrial society, appearing late in the historical sequence, may nevertheless produce—through its uniform repetitive tasks and its social institutions which reduce the opportunity for individual choice—far less individualized personalities than an earlier society without mass production. It depends on the particular organization of society whether the trader, for example, grows acutely aware of the difference between his own interests and the interests of others, as he did under *laisser-faire*, or whether he thinks rather in terms of collective action by a group of associated merchants or a guild of craftsmen.

As a member of our contemporary culture, Prof. Mannheim is ready to agree that he, too, values the eight tendencies which Prof. Flugel identified. But as a sociologist he challenges the frame of reference within which the psychologist makes his judgments.

Dr. Thouless, in his comment on Prof. Flugel's paper, not only objected to the suggestion that the eight tendencies represent 'progress', but also doubted whether they are all aspects of any single process or at all closely related with one another. For example, one might go far towards realistic thinking (3) without becoming any less aggressive (4). Rather than assume a unified stream of progress we should do better to recognize that there are many ways in which men and societies can improve.

Like Prof. Mannheim, Dr. Thouless stressed the limitations of moral judgments made within our contemporary frame of reference. Thus our own readiness to talk as if aggressiveness were the principal evil may seem to later observers as relative and

peculiar a characteristic as the nineteenth century's readiness to regard sexual indulgence as the chief of sins. Again, the sense of guilt has gone through cultural vicissitudes. Puritanism made it a moral good in itself. Psycho-analytic writers now speak as if it were merely pathological. But it has a valid function to perform: it can serve to deter us from a repetition of those acts which we ourselves condemn. In fact, in Dr. Thouless's opinion, the modern tendency to belittle the idea of sin goes too far. The fact of sin (whether we take a religious view of it or not) occurs whenever a man's voluntarily controlled behaviour falls short of his own accepted standards. Even in these modern times, we retain a vivid sense of sin when others commit it; nowadays a man is prone to repent of his neighbour's sin and to apply the light of scientific understanding to his own.

In general, Dr. Thouless believes that the psycho-analytic approach represented by Prof. Flugel's eight principles suffers from an intellectual bias. It describes moral betterment as if that were primarily a matter of getting better principles and moral ideas, and seems to neglect the problem of bringing actual behaviour into line with those moral principles. For this reason he proposed the ninth tendency already referred to—a progressive increase in the voluntary control of conduct. But, as he was careful to point out, this trend by itself does not ensure an improvement in conduct, since voluntary effort may be directed towards wrong ends. The ethical questions remain.

The meeting was left to decide whether, as Dr. Thouless suggested, the effort to discuss the nature of right and wrong in the new technical language of psycho-analysis is primarily a test of the adequacy of that language; or whether, as Prof. Flugel holds, certain psycho-analytic conceptions, such as that of the super-ego, actually throw new light on moral problems.

# OBITUARIES

## Prof. Gustav Gilson

NEWS comes from Belgium that M. Gustav Gilson, embryologist at Louvain, fisheries expert at Ostend, died last winter. He was eighty-two years old, and though he kept busy to the end the best of his work was done well-nigh sixty years ago.

Gilson was Carnoy's favourite pupil: when Carnoy started his famous journal, *La Cellule*, Gilson figured as co-editor, and the first number contained his "Etude comparée [or part of it] de la Spermatogénèse des Arthropodes". The next was by Carnoy himself, "Sur la cytodiérèse chez les Arthropodes", in other words, on mitotic cell-division. It was a great enterprise to start this costly journal in a small university like Louvain; but natural science was no new thing in that University. It was there that Theodor Schwann wrote his "Observations microscopiques", and laid the foundations of the cell-theory. P. J. van Beneden had been professor there for forty years, and his "Ostéographie des Cétacés" was famous. His son Edouard was a leading embryologist of F. M. Balfour's time, and had just published a paper which became classical, on the egg of *Ascaris megalocephala*; but he left Louvain for Liège (as Schwann also had done), and Louvain and Liège seldom saw eye to eye. Other papers of Gilson's, more or less important at the time, were for example on "Les glandes odorifères de Blaps mortisaga" (1886); a whole series on "La soie et les appareils séricigènes" (1890–94); and a careful histological study of "Les cellules musculo-glanduleuses de l'Owenia", a genus of Annelides (1898). When Carnoy died all too soon in 1899 Gilson pronounced the customary *Éloge*, and did it with grace and tenderness: he carried on *La Cellule* as sole editor until it came to an end, like much else in Louvain, during the War of 1914–18.

Gilson carried on the Department of Zoology well and efficiently, but did little more histological or embryological work after Carnoy's death. He had a family connexion with Ostend, and the latter years of his life were spent there; he began to interest himself in the local fisheries, and in course of time established a Fisheries Laboratory, and even issued a journal (*Annales de l'Institut*) in connexion with it. He was not one of the founders of the Conseil International, but he took part in our second meeting in Copenhagen (1903), and attended regularly thereafter. One of the first of his fishery publications was on the reproduction and migrations of the eel, a burning question at the time; another, about 1910, was an elaborate statistical study of the great plaice-fishery; yet another, and an interesting one, was on the 'Guai', or winter-herring of the Belgian coast. Other fishery papers mostly dealt with the busy fleet of motor and sailing cutters, trawling and shrimping off the Belgian coast, and landing, or still worse destroying, prodigious quantities of 'undersized' fish. A report which he made to the Council in 1928 was the completest account of such a fishery that had ever been drawn up, and the many million of small fish destroyed made a startling story.

Gustav Gilson married late in life, but very happily. He was reticent of speech, austere of manner, of grave and intellectual countenance; during fifty years acquaintance I found him a faithful friend, a real scholar and a true man.

D'ARCY W. THOMPSON.

## Mr. H. Tetley

MR. H. TETLEY, curator in zoology at the Bristol Museum and Art Gallery, died on September 26 at the relatively early age of fifty-four. Educated at Malvern College and graduating B.Sc. in the University of Leeds in 1916, he carried out postgraduate research in entomology in the University of Manchester. During the War of 1914–18 he served as a paymaster in the R.N.V.R. and on demobilization was appointed assistant demonstrator in zoology and curator of the zoological museum in the University of Sheffield.

After a serious illness—the effects of which really undermined his health for life—Tetley was appointed in 1927 to take charge of the Zoological Department of the Bristol Museum and Art Gallery. There he overhauled the extensive collections, prepared and arranged new exhibits, and instituted the organization of records concerning the local distribution and occurrence of many groups of animals. It was a severe blow to him when in 1940 many of these records and much of the collections were destroyed by enemy action. He was especially conversant with local birds and mammals, and his publications reflect these interests. Many of these papers were published in the *Proceedings of the Bristol Naturalists' Society*, and by far his most important work was an

extensive paper on the "Land Mammals of the Bristol District" published in 1940. Papers on British pole-cats, the Scottish fox and wild cat were published in the *Proceedings of the Zoological Society* between 1939 and 1941 and various notes appeared between 1933 and 1942 in *British Birds*.

Tetley was a first-class observer in the field, and was always ready to place his comprehensive knowledge of local animals at the service of interested inquirers. Many of his papers bear witness to these detailed observations, while others give evidence of his bibliographical researches and are fundamentally compilative in character.

He held several offices in the Bristol Naturalists' Society, being president at the time of his death. He was a fellow of the Zoological Society of London and was recently engaged upon collecting details for the third volume of the International Wildfowl Inquiry Committee and the University of Bristol sub-Committee of the Nature Reserves Investigation Committee. For several years he had been special lecturer in systematic zoology at the University of Bristol, where he also rendered valuable service in connexion with the Wiglesworth Library of Ornithology.

Dogged by ill-health, never strong and robust, Tetley carried out his duties faithfully even under adverse conditions. Of a gentle disposition, though rather non-receptive to new ideas and policies, he was held in high esteem by local naturalists, and the sympathy of his colleagues and friends is extended to his widow and two children.

F. S. WALLIS.

---

WE regret to announce the following deaths:

Prof. C. G. Barkla, F.R.S., professor of natural philosophy in the University of Edinburgh, on October 23, aged sixty-seven.

Dr. Olaf F. Bloch, formerly chief chemist of Ilford, Ltd., on October 19, aged seventy-two.

Prof. M. R. Wright, M.B.E., emeritus professor of education, University of Durham (King's College, Newcastle upon Tyne), on October 10, aged ninety.

# NEWS and VIEWS

## Prof. H. T. Flint

PROF. H. T. FLINT, the new occupant of the Hildred Carlile chair of physics in the University of London in succession to Prof. W. Wilson, was one of the latter's colleagues at King's College, London, in the days immediately following the War of 1914–18. Like his predecessor, he is chiefly interested in the theoretical aspects of physics and has made many highly original and important contributions to relativity and quantum dynamics. He showed that Wilson's quantum conditions fix an upper limit to the number of the chemical elements and gave an explanation of the existence of the elementary charge. The introduction of a matrix-length into the geometry of the microphysical world and of the imaginary gauge is due to him, and his work has anticipated much of recent nuclear field theories.

Prof. Flint's activities are by no means confined to theoretical subjects. He has recently devised a new method of measuring dielectric constants and absorptions, which has the merit of eliminating errors due to fluctuating input and enables dielectric properties in the region of centimetre, or even millimetre, waves to be investigated. He is also an expert on the manipulation of radium for hospital purposes. He is the author of well-known works on wave mechanics, geometrical optics and, in collaboration with Dr. Worsnop, of a much used text-book of practical physics.

## International Convention for Civil Aviation

A WHITE PAPER, issued recently, lays down the British Government's policy for the future control of civil aviation. It visualizes a radical change from the pre-war outlook, proposing a new air convention covering six main objectives to be secured by international agreement. Proposals have already been made by the Canadian Government, and other Commonwealth Governments are known to hold favourable views. Previous to the War, regulation by agreement was confined to technical aspects covering safety, the right of innocent passage across territory and access to aerodromes. This convention, although ratified by thirty-three States, was never adopted by the United States, the U.S.S.R. and China. Many countries heavily subsidized their air-transport companies, either for national prestige or war potential, and consequently bargaining for international flying rights became political and gave rise to much friction. The new proposals would cover the economic and commercial, as well as the technical aspects, and thus by agreement avoid the political and narrow national outlook in administering air transport over world routes.

The British Government suggests that the proposed convention will secure the following objectives: (1) meet the needs of the world for plentiful, efficient and cheap air transport; (2) maintain equilibrium between the world's air transport needs and capacity; (3) ensure an equitable participation of each country in the world's whole air transport scheme; (4) eliminate wasteful competition and in avoiding unnecessary expenditures and fixing rates of carriage, limit the need for, and to control, subsidies; (5) standardize technical matters dealing with the safety of flight; (6) contribute to world security by encouraging international travel and exchange. It is suggested that the administration should consist of an international air authority, with operational executive panels, probably regional, and sub-commissions to deal with technical matters. The authority would consist of representatives of the ratifying States, and would need to be placed in proper relationship to any world security organization as may exist. The composition of the executive and technical bodies would have to be by mutual agreement between the air authority and the ratifying powers. The Government has explained that these proposals are a broad outline only, and may need to be modified in the light of views expressed by other countries.

## Gift to University of Leeds

MR. CHARLES BROTHERTON has just given the University of Leeds (1) £1,000 a year for seven years for the establishment of a Brotherton research fellowship in physical chemistry tenable in the Department of Colour Chemistry and Dyeing; (2) £1,000 a year for seven years for the establishment of a new lectureship in chemical engineering in the Department of Coal Gas and Fuel Industries; and (3) an additional sum of £1,000 to each of the two Departments for the purchase of equipment.

These are not the first gifts which have come to the University of Leeds from Mr. Brotherton. In September 1940 he provided a valuable addition to the resources of the Colour Chemistry and Dyeing Department by providing funds for the institution of two Charles Brotherton entrance scholarships tenable by students reading for the degree of B.Sc. with honours in colour chemistry, and two years later he increased the number of scholarships to three. Mr. Brotherton has expressed his gratification at the success of this scheme and has now extended his interest in the work of the Department by his further contributions. For some time past the investigation of problems of fibre technology, dyeing and some aspects of colour chemistry has necessitated the increasing application of methods of physical chemistry. The addition of a physical chemist to the staff of the Department has long been desirable; but the mere institution of such a post would have been ineffective in the absence of a suitably equipped laboratory. Mr. Brotherton's generous gift, which allows complete freedom in the expenditure of the funds as between the salary of the research fellow and the equipment of an appropriate laboratory, will make possible at an early date the realization of this most important development.

The Department of Coal Gas and Fuel Industries with Metallurgy, which also benefits by Mr. Brotherton's latest gift, co-operates with the Institution of Gas Engineers in research supported by the Institution and guided by a joint committee of the Institution and the University of Leeds. The Livesey professorship was endowed in 1908 from a fund raised by public subscription from the gas industry in memory of the late Sir George Livesey. The Department has for some thirty-seven years provided degree courses in fuel and metallurgy. The training in gas engineering has been based on chemistry and engineering, followed by instruction embracing chemical engineering and fuel technology, mainly to meet the needs of the gas industry. A separate curriculum was established in 1942 in chemical engineering and is intended to provide instruction particularly in plant design and in the so-called unit processes of the chemical industry. It meets the special need of those passing either into the contracting side of the gas industry or into the chemical industry generally. The provision of up-to-date equipment and staff in such technological departments is costly, and the University has largely to rely on the support of industry. Mr. Charles Brotherton's generous gift to provide for the special needs of chemical engineering is most opportune and should materially help to establish one of the best training grounds in the country. The need is vital, for British universities have been unable during the years between the two wars to make advances in this field comparable with those of the United States.

## An International Association of University Teachers

THE sixth general meeting of the Association of Allied University Professors was held in London on September 25. The meeting was called specially to consider the statutes for a proposed International Association of University Professors and Lecturers. These were, after some amendment, adopted as provisional statutes, so that what has hitherto been a domestic association, bringing together those university professors and lecturers of the Allied countries who, in recent circumstances, have reached Great Britain, now takes on a wider international function under a new name. It is hoped that in each country where there is academic freedom a national group of members may come into existence. In order to establish contacts and bring into being such groups, a Provisional Central Council has been formed, mainly of university teachers of various nationalities who are domiciled in Great Britain, the duty of each member of which is to arouse interest in the Association in the universities of his own country. As soon as circumstances permit, representatives from these countries will replace the original provisional member and the Central Council will become a representative body, and will confirm or amend the statutes. The Provisional Central Council at present comprises members representing some twenty different countries, and it will be enlarged as further contacts are made. One result of the change in structure of the Association will be that in Great Britain, where membership has hitherto been restricted in order to preserve some balance between British members and those from other countries, membership will now be widely open in university circles. After the more formal business of the meeting was completed, Dr. Grayson N. Kefauver, of the American Educational Delegation, gave an address on "The Role of the University in Social Reconstruction".

## British Standards Institution

THE annual general meeting of the British Standards Institution was held on October 17, when Lord Woolton was elected president, Sir Percy Ashley vice-president, and Sir William Larke succeeded Sir Percy Ashley as chairman of the General Council. Dr. E. F. Armstrong, chairman of the Finance Committee, explained that the income and expenditure for the year had increased by 28 per cent and was now about £69,000. The sales of copies of British Standards had gone up 39 per cent. The Government grant-in-aid was nearly double and was now £12,900. While there was an increase of some 15 per cent in the number of subscribing members he pointed out the need for greater support from local authorities and industry. Sir Percy Ashley concluded his term of office as chairman of the General Council with a brief review of the work done as a direct aid to the war effort by the British Standards Institution, and the progress made during the same period in the preparation of British standards for industrial and commercial materials and appliances. The war work covered the preparation of war emergency British standards for A.R.P. materials for the Ministry of Home Security, packaging schedules and code for the Ministry of Production, steel and non-ferrous metal standards as well as standards for many other materials, tools and appliances for the Ministry of Supply and for the Services generally, and schedules for clothing and hardware for the Board of Trade. Many of the war emergency standards were made

compulsory by the issue of statutory rules and orders. The preparation of standards for building materials and appliances now being carried out in support of the programme of house-building of the Ministries of Works and Health has already reached substantial proportions. Sir Percy concluded by emphasizing the importance of industrial standards, which provide for accurate and precise trade descriptions, methods of sampling and testing, and standards of performance, and of an independent body, set up and maintained by the national industry as a whole, with Government support but not under Government control, for the preparation of such standards. Progress will be most widespread and continuous if the policy of 'standardization by consent' is consistently pursued.

### Harvesting Machinery

THE inaugural meeting of the 1944–45 session of the Institution of British Agricultural Engineers was held on October 17 at the Institution of Electrical Engineers under the chairmanship of Mr. C. I. C. Bosanquet, and Mr. Cornelius Davies read a paper on harvesting machinery. Mr. Davies, who has for many years been closely associated with the South-Eastern Agricultural College at Wye, Kent, traced the developments in methods of harvesting from the earliest times to the present day. His paper dealt not only with the harvesting of corn and potatoes but also with machinery for handling sugar beet, grass, silage, hops, vegetables and fruit. On the combine harvester Mr. Davies reminded the audience that this machine cuts and threshes the grain in one operation, and there is no period in the stook when final ripening can take place. Adequate drying facilities are necessary, and serious attention to grain storage is required. Nearly all combine owners are faced with a straw problem. He considers that to burn straw is evidence of bad husbandry. On some farms pick-up balers are used, but the cost of these is nearly as high as that of a combine; further, the use to which the baled straw can be put must be considered.

On the question of potato harvesting Mr. Davies discussed the relative merits of the spinner and the elevator lifter, and stressed the need that still exists for a really satisfactory potato harvester. In conclusion, Mr. Davies stated that in addition to the provision of more and better harvesting machines, there must be more skill in handling and greater care in maintaining and managing agricultural machinery. In the discussion which ensued, community ownership of expensive machines, the employment of contractors, and the development of simple and relatively inexpensive machines within the scope of private ownership on small farms were discussed.

### Cultural Co-operation

UNDER the title "The Cultural Co-operation Program 1938–1943" (Washington: Govt. Printing Office. 15 cents), the U.S. Department of State has issued a report by H. Hanson describing the development since its inception of this programme for fostering international relations on a basis of mutual understanding and appreciation. The programme is conceived by the General Advisory Committee of the Division of Cultural Relations as a long-term one of continuing activities which should be as broad as intellectual and cultural activities themselves. A statement of policy issued by the Department on March 31, 1944, on the participation of the United States in educational and cultural reconstruction in Europe, indicated the Department's intention of co-operating in the formation of a United Nations organization for educational and cultural reconstruction. This emergency programme to meet this need may consist of assistance in restocking essential educational facilities, especially books and scientific and other teaching aids; in the provision of opportunities for training carefully selected foreign students in American educational institutions; in re-establishing essential library facilities; and in the recovery and restoration to their rightful owners of scientific, artistic and archival materials looted by the Axis countries. The report includes some notes on professional and scientific relations, and on the various activities under the programme: these include travel and study grants, including student exchange, and the provision of technical experts for China; cultural centres, such as libraries, including the reference library opened by the Office of War Information in London in December 1942, which seeks by a careful loan service to place each new American book in the hands of selected people in the British Isles; cultural materials, such as books for libraries in the Western hemisphere, book translations, microfilms for China and the Near East, science news letters and motion pictures and radio activities.

### Pitfalls of Positivism

IN a most timely article entitled "Positivism" (*Mind*, July 1944), Prof. W. T. Stace throws great light on the doctrinaire character of the so-called logical positivists. After making a useful distinction between the 'meaning' of a word and the 'significance' of a sentence, he states the positivist principle as follows: "what makes a sentence significant is that some actual or possible observation can be deduced from it in conjunction with certain other premises, without being deducible from those other premises alone". He then makes his main point, that underlying this principle is another one more fundamental, which he calls the "Principle of Observable Kinds", and states as follows, "a sentence, to be significant, must assert or deny facts of a kind such that it is logically possible directly to observe some facts which are instances of that kind".

Prof. Stace points out that this principle is different from the positivist principle in that it introduces the notion of direct verification, whereas the positivist principle makes use of that of indirect verification. Further, this latter principle neither follows from the positivist principle nor is it self-evident. Nor again does it follow from the empiricist principle which states that all our simple ideas come from impressions, because this provides no guide as to how the former are to be combined to make significant sentences. In fact, Prof. Stace holds that there is no reason to think the principle true. It would follow that we should discard it and with it the positivist principle, if in fact this latter is based on it. But the proof which Prof. Stace gives that the two are related in this way is weak. Nevertheless, all those inclined to flirt with modern forms of positivism should study the article.

### Physical Society's Exhibition of Scientific Instruments and Apparatus

THE Physical Society's long and almost continuous series of annual exhibitions of scientific instruments and apparatus was, of necessity, suspended during the War. Its resumption has recently been considered by the Council of the Society and by the Exhibition

Committee, now under the chairmanship of Prof. G. I. Finch, who succeeds the late Mr. R. W. Paul, and it is proposed that the thirtieth exhibition (which was planned to take place in January 1940) shall be held in January 1946. It will take place in the Physics Department of the Imperial College, Imperial Institute Road, London, S.W.7, as on previous occasions, and will be on about the same scale as the exhibitions of the immediate pre-war years.

## Edward Emanuel Klein, F.R.S. (1844–1925)

DR. EDWARD EMANUEL KLEIN, a pioneer in histological and bacteriological research, was born at Ersek in Hungary on October 31, 1844, and studied at Vienna, where he devoted himself to microscopic anatomy. In 1869 he came to England and served at first as histological assistant to Burdon Sanderson, but afterwards devoted himself entirely to bacteriology, of which he was the first representative in England. He was lecturer in histology and later of bacteriology at St. Bartholomew's Hospital Medical School, where Ronald Ross was one of his pupils. He was the author of "The Anatomy of the Lymphatic System" (1873–75), "Atlas of Histology" with Mr. Lobb Smith (1879–80), "Elements of Histology" in collaboration with J. G. Edkins (1883), "Micro-organisms and Disease" (1884), "Asiatic Cholera" (1884) and "Oriental Plague" (1906). He was also collaborator in a "Handbook for the Physiological Laboratory" (1873). He was elected a fellow of the Royal Society in 1875. He died at Hove on February 9, 1925.

## The Night Sky in November

NEW moon occurs on Nov. 15d. 22h. 29m. U.T. and full moon on Nov. 30d. 00h. 52m. The following conjunctions with the moon take place: Nov. 5d. 00h., Saturn 0·1° N.; Nov. 10d. 18h., Jupiter 4° S.; Nov. 17d. 05h., Mercury 5° S.; Nov. 19d. 02h., Venus 3° S. The following occultations of stars brighter than magnitude 6 take place: Nov. 2d. 23h. 12·0m., *i* Tauri (*R*); Nov. 3d. 22h. 06·1m., 20° 1105*m* (*R*); Nov. 8d. 04h. 19·1m., 8 Leon. (*R*). The times refer to the latitude of Greenwich and *R* refers to reappearance. Mercury sets 8 minutes after the sun on Nov. 1 and 52 minutes after the sun at the end of the month. Venus can be seen in the evenings, setting at 17h. 45m., 18h. 12m., and 18h. 18m. at the beginning, middle and end of the month respectively. Mars is too close to the sun for favourable observation. Jupiter rises at 2h. 19m. at the beginning of November and can be seen about midway between $\sigma$ and $\upsilon$ Leonis. At the end of the month the planet has moved into the constellation of Virgo and rises at 0h. 48m. Saturn, in the constellation of Gemini, sets at 12h. 09m., 11h. 12m. and 10h. 11m. at the beginning, middle and end of the month respectively. The times have been computed for the latitude of Greenwich and the effects of refraction are ignored in all cases. The Leonid meteors are due on November 13–14 but the shower has been very feeble for some years, and the same remark applies to the Andromedids, which were once fairly active during November 18–27.

## Announcements

AT a meeting of the Council of the Royal Society held on October 12, amendments were made to the statutes so as to make it clear that, since the passing of the Sex Disqualification (Removal) Act of 1919, there is no barrier to the admission of women into the fellowship of the Society. This decision was reached after the fellows of the Society had been consulted by postal vote and had approved the amendments ratified by the Council on that day.

THE U.S. National Academy of Sciences, which serves as an official liaison agency between American scientific men and the Government, is to receive the Ordnance Distinguished Service Award of the U.S. Army. In a letter to Dr. Frank B. Jewett, president of the Academy, Maj.-General L. H. Campbell, jun., Chief of Ordnance, says: "It is my pleasure as Chief of Ordnance of the Army to tell you on behalf of the Ordnance Department that I am most grateful for the outstanding contributions the National Academy of Sciences has made to Ordnance progress in this war. The degree of that progress is best shown by the success of our fighting forces in all theaters of operations".

THE Lord President of the Council has appointed Sir Robert Robinson to be chairman of the Water Pollution Research Board of the Department of Scientific and Industrial Research, in succession to the late Mr. H. C. Whitehead.

MR. A. V. WILLIAMSON, reader and head of the Department of Geography of the University of Leeds, has been elected to the newly instituted chair of geography, as from the beginning of the present session. The title of honorary reader in the history of economic theory in the University has been conferred on Mr. H. D. Dickinson, lecturer in economic history.

SIR SAMUEL COURTAULD has offered the University of Oxford £2,000 a year for seven years, for research into the relative efficiency of small- and large-scale business and allied problems of industrial structure and organization and kindred subjects, to be carried out under the direction of the warden and fellows of Nuffield College.

FOR the third successive year, a course of lectures on the application of statistical methods to industrial problems is being given by Dr. B. P. Dudding at the University of Sheffield on Friday evenings, commencing October 20. These lectures are of a rather more advanced type than those given in earlier courses and although primarily intended for students of engineering are open without charge to suitably qualified men from industry.

THE following scholarships, which are tenable for three or four years, according to the length of the course at the university selected, will be offered for competition by the Institution of Naval Architects in 1945: Martell Scholarship (£130 per annum); Trewent Scholarship (£125 per annum) in naval architecture; Denny Scholarship (£130 per annum) in marine engineering. The Denny Scholarship, age limit nineteen, is tenable for four years at the University of Glasgow only, with apprenticeship of five years. Entries for the Martell Scholarship close on January 15, and for the other Scholarships on May 31. The Wrought Light Alloys Development Association Research Scholarship (£400 per annum, tenable for two years) is to be awarded to graduates in applied science preferably less than thirty years of age on October 1, 1945: entries close on July 31. Particulars can be obtained from the Secretary of the Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

## Filamentous Carbon

P. AND L. SCHÜTZENBERGER[1] reported that when cyanogen was passed down a porcelain tube containing gas carbon with powdered cryolite on its surface, heated to a cherry-red heat, decomposition occurred and elementary carbon separated in a bulky mass of very slender filaments. The filaments had some elasticity, were friable and marked paper. When aluminium was mixed with the gas carbon, non-elastic filaments separated round it which, on gentle compression, resembled graphite.

FIG. 1.

This filamentous or woolly form of carbon is sometimes found in beehive and recuperative coke-ovens, particularly near the ascension pipe. C. and H. Pélabon[2] found that the wool consisted chiefly of grey cylindrical threads with a glazed surface and occasional bundles of much finer threads. The average length of the threads was 5 cm. and the diameter varied between 0·03 and 0·15 mm., the finer threads being only about 0·002 mm.

A similar filamentous form of carbon has been obtained by cracking methane, diluted with nitrogen, hydrogen and carbon monoxide on an iron surface at 1,000° C. The bulk of the carbon was deposited in the form of a hard, brittle, grey mass, on the surface of which was a large number of slender carbon filaments all running more or less parallel to each other (Fig. 1). These filaments are very fragile, but we succeeded in mounting a small bundle of them and taking an X-ray photograph. Unfiltered cobalt $K$-radiation was used with a specimen to film distance of 48 mm. The photograph (Fig. 2) indicates that the carbon present is the ordinary 'amorphous' variety ($\theta_{002} = 14 \cdot 8°$, inter-layer plane spacing about 3·5 A.) with the $c$ axis perpendicular to the fibre axis, that is, the hexagon layer planes more or less parallel to the fibre axis, with a maximum deviation of about 30°.

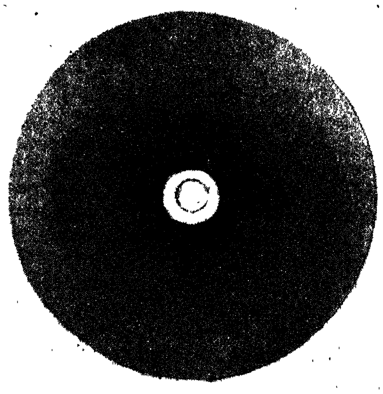

FIG. 2.

So far as we know, this is the first example of a fibre built up from lamellar units.

## The Divergence Difficulty of Quantized Field Theories

IN the theory of interaction of particles like photons and electrons or mesons and nucleons, etc., the experiments are always made in such a way that the different kinds of particles are observed in different parts of space with different instruments. In these parts of space one can speak of pure kinds of particles and describe them by pure quantized fields—Maxwell's field, Dirac's field, etc. However, in the part of space where the collisions really take place, the pure fields are not simply additive but have to be supplemented by an interaction field. All effects due to the interaction can be obtained by considering the stationary states of the whole system.

Because of the complication of the problem, one has to use a method of successive approximation called the perturbation method in which the interaction is regarded as small. It is well known that then special care must be taken to remove the degeneracy of the states of the unperturbed system in a way so as to anticipate the eigenstates of the perturbed system. This preliminary step has, however, been ignored in the usual practice for the interaction of fields; and consequently divergent expressions appear as soon as the next higher order of the perturbation method is attempted.

The results obtained by the usual practice were in good agreement with observations in the case of the photon-electron interaction, although the divergence of the higher approximation indicates that some mistake must have been made, which might be physical or mathematical. No such agreement with observation has been found in the case of the meson field. Some time ago an improved method[1] based on physical reasoning was developed which takes account, to the first approximation only, of what is classically known as the 'radiation reaction'. This method is well confirmed by its applications, especially to the meson field, but hitherto its theoretical basis was not satisfactorily established.

It has now been found that this provisional method can be rigorously established by a systematic application of the ordinary perturbation theory for degenerate systems adapted to the case of the continuous

spectrum. I have found that the treatment of the radiation reaction referred to above constitutes exactly the preliminary step of the removal of degeneracy. The continuation of the perturbation method to higher approximations is then possible without any difficulty.

With this mathematical improvement, it might be that the present field theories (without any change—such as that proposed by Dirac[2], or that by Born and Peng[3]) are sufficient to explain most of the known facts. For example, the anomalous value of the magnetic moment of the proton or the neutron can now be rigorously dealt with. It seems possible that the infinite self-energy of the point electron, which has always been a difficulty in the classical theory, will also become finite in the quantum theory.

## Interpretation of Patterson Diagrams

UNDER this title, Robertson[1] has published a simple optical method of constructing Patterson diagrams. Hägg[2] has suggested a modification of this method. Bragg[3] described a further improvement by the introduction of a lens in the path of the light rays, so that both patterns, the diagram of which is required, are on the same scale. The Patterson is then formed in the focal plane of the lens, and can be photographed, viewed on a screen or with the aid of an eyepiece. The whole arrangement then consists of an ordinary camera or telescope, in front of which are held two identical and properly oriented patterns. The scale of the Patterson can be varied by varying the distance in between the patterns. If the aperture of the lens is made large enough to accommodate all the relevant rays, the second screen need not be in contact with the lens. If punched screens are used, the only disadvantage is the lack of continuous adjustment of the pattern, possible in the original sphere and thread method of Robertson.

Very interesting arrangements are obtained if one of the patterns is replaced by an image of the other pattern in a plane mirror $M$ (Fig. 1). One pattern only is then necessary. The illumination can be obtained by means of a 45° glass plate $G$ (see Fig. 1$a$), in between the pattern and the objective $L$. If movable opaque disks are placed at $BB'$, black spots will appear on a bright background at $AA'$. The Patterson resulting from this arrangement at $CC'$ has unfortunately very poor contrast, peaks in the Patterson appearing as only slightly more luminous spots on an already luminous background. If an opaque sheet in which holes are punched is placed at $BB'$, bright spots on a dark background will appear at $AA'$, and the Patterson at $CC'$ would have luminous peaks on a black background, thus giving a very good contrast. However, the virtue of the continuous adjustment possible with disks is lost.

Another arrangement is represented in Fig. 1$b$. The atoms are here represented by disks, the upper surfaces of which are blackened, and the lower surfaces whitened. The white sides illuminated from below would appear at $AA'$ as bright spots on a black background, and the Patterson at $CC'$ would have peaks represented by darker spots on a bright background. This arrangement has the advantage of the continual adjustment, for example, by placing movable disks on a glass plate $P$.

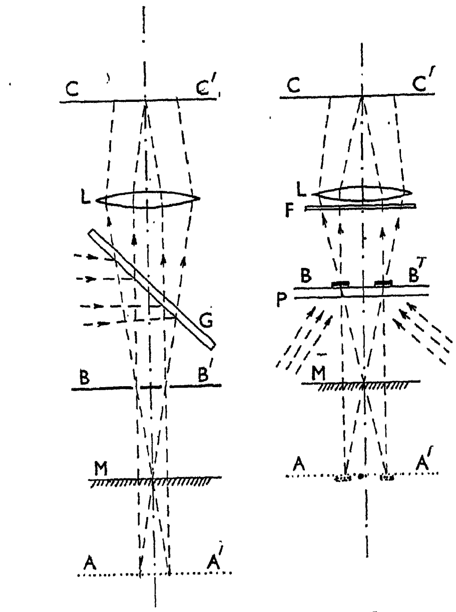

FIG. 1. THE CONSTRUCTION OF A PATTERSON DIAGRAM BY MEANS OF A MIRROR IMAGE. (a) ILLUMINATION BY 45° GLASS PLATE. (b) ILLUMINATION OF FLUORESCENT DISKS FROM BELOW.

In this method, the appearance of the Patterson is that of a negative of the pattern produced by a punched screen, the central peak being completely dark in the middle. This kind of pattern, although representing the Patterson function faithfully in terms of the difference of light intensities, is in some cases not so suitable for a direct visual examination as the positive pattern produced by the first method using a punched screen, due to the non-linear (logarithmic) response of the eye to the light intensity. However, if a photograph is taken, it is easy to examine either the positive or the negative, and both methods are equivalent in performance. In the second method, care must be taken to provide uniform illumination of the disks and at the same time to prevent the light from the light source entering the objective directly. This can be most conveniently overcome by using a mercury ultra-violet lamp with a Wood's glass filter for the illumination of the disks at $BB'$, and by painting the under sides of the disks with a yellow fluorescent paint. If a yellow filter $F$ is placed immediately in front of the objective, the direct radiation from the lamp will be cut off, and only the yellow light emitted by the disks would enter the objective. A contrast image is thus obtained.

Pattersons corresponding to two-dimensional multicellular structures are sometimes needed, whereas methods using continuous adjustment are practicable for the production of a Patterson of a single cell only. A Patterson of a multicellular structure can be easily obtained by superposition of a properly spaced double array of Pattersons of a single cell, the spacing in the array being equal to the lattice spacing of the original lattice. As the single-cell Patterson is twice the size of the original cell, the superposition of only four single-cell Pattersons would give in the central overlapping part all the informa-

tion needed. The superposition can be conveniently achieved photographically by successive exposures on the same plate.

## Elastic Constants of Diamond

BY using a suitably cut and silvered quartz or tourmaline wedge, we have been able to generate continuously varying ultrasonic frequencies. This forms the basis of a new method for measuring the effective elastic constant of a given plate. In this method, the particular frequency for which there is best transmission through the plate is located by allowing the waves to pass through the plate into a liquid and observing positions of maximum intensity in respect of the usual Debye–Sears pattern. This frequency $\nu$ is related to the effective elastic constant $C'_{33}$ by the relation $4\nu^2d^2\rho = C'_{33}$, where $d$ and $\rho$ are respectively the thickness and the density of the plate.

By making such observations on an octahedral and a dodecahedral plate of diamond, two independent effective elastic constants have been obtained. It is not possible to get the third one by this method, but by combining the results with the known bulk modulus $5 \cdot 9 \times 10^{12}$ dynes per sq. cm. (which represents the mean of observations by Adams[1] and by Williamson[2]), the following values expressed in dynes per sq. cm. have been obtained for the elastic constants of diamond:

$C_{11} = 9 \cdot 4 \times 10^{12}$; $C_{12} = 4 \cdot 2 \times 10^{12}$; $C_{44} = 4 \cdot 2 \times 10^{12}$.

These results are now reported in view of their importance, but their significance will be discussed and the details of the method given in a fuller paper in the *Proceedings of the Indian Academy of Sciences*. It may be remarked here that we have found these elastic constants to be in satisfactory agreement with the force constants derived from the known frequencies of the diamond lattice.

## A Reversible Contraction Phenomenon in Animal Hairs

ALTHOUGH the action of cuprammonium hydroxide on cellulose has been studied in considerable detail, comparatively little is known of its effect on keratin, except that under certain conditions hair and wool can be dissolved in the reagent[1,2]. It is therefore of interest to describe some observations on the action of cuprammonium hydroxide on wool which promise to yield valuable information on the mechanism of long-range elasticity in animal hairs and on the structure of proteins.

If a wool fibre (Lincoln) is immersed in a solution prepared by dissolving purified copper hydroxide in concentrated ammonia solution, it will, after a time depending on the copper content of the solution, become stained greenish-blue and contract in length. Prolonged washing in water fails to remove the stain and has little effect on the length, although a further small contraction may occur. Under the correct conditions it is possible to realize in this way a contraction of 28 per cent of the initial length. If the fibre is now placed in a dilute solution of sulphuric acid for a few minutes, the blue stain disappears and the fibre returns practically to its original length. Subsequent washing in water produces no further change in colour or length. The power of the fibre to recover its original length depends on the severity of the treatment; after prolonged immersion in concentrated solutions the recovery may stop when the fibre is still some 10 per cent shorter than the initial length. Even though the fibre retains its power of recovery, it is weakened by the treatment with cuprammonium hydroxide, and evidently side-chain breakdown takes place in the solution.

The dimensional changes are accompanied by changes in the X-ray photograph, which becomes weaker and vaguer without loss of orientation or pronounced spacing changes, until, when the contraction is a maximum, it has almost disappeared. This is in striking contrast to the effects in ordinary supercontraction, where the normal $\alpha$-photograph may still be present for contractions of the order of 20 per cent, although the disoriented $\beta$-photograph may appear under certain conditions[3]. After acid treatment to remove the copper, the $\alpha$-photograph returns, comparable in every way with the original photograph. This sequence can be repeated several times.

The coloration of the fibres after treatment with cuprammonium hydroxide and washing in water is clearly due to the adsorption of copper. Our measurements showed that the amount of copper adsorbed under conditions corresponding to those giving maximum contraction is about 29 per cent (by weight, calculated on the dry weight of the fibre), the observed values lying between 26 and 32 per cent for different concentrations of the reagent. This corresponds approximately to one copper atom per two amino-acid residues. The total increase in weight (40 per cent) suggests that the copper is present as a complex.

The observed contraction may be attributed to the powerful attraction of the copper for the appropriate active groups (for example, amino- and imino-groups) in the keratin complex. This contraction would be resisted by those side-chain cross-linkings between the polypeptide chains which are not broken by the reagent itself, and at first enough would be left stressed but unbroken to assure the return of the fibre to the initial length on removal of the copper. Prolongation of the treatment, however, would ultimately reduce the number of unbroken cross-linkings below the minimum required for complete recovery.

We have observed a similar phenomenon in fibres treated with solutions of some, but not all, related copper compounds.

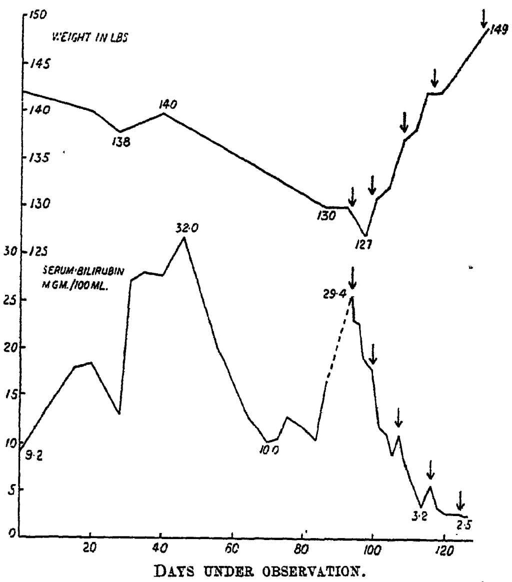
## The Sulphur-containing Amino Acids in Jaundice

We have read with interest the letter from Peters *et al.* on "The Sulphur-containing Amino Acids in Jaundice"[1]. The authors would appear to have misunderstood the statements made in our previous note[2] concerning the value of methionine treatment. We said only "that results would appear to show that the clinical course is influenced beneficially and the period in hospital significantly shortened". This statement is supported rather than contradicted by the data contained in their note, though statistical analysis of figures based only on serum bilirubin levels may not yield entirely reliable results. We would like to repeat our claim that "in *gravely ill* patients, the results obtained by methionine treatment have been so striking as to leave no doubt as to the efficacy of the treatment especially in those cases which have remained jaundiced for weeks or months". Such cases, we note, were not included by Peters *et al.* in the 150 cases selected by them for statistical analysis. They are, of course, not susceptible to statistical analysis, yet it is precisely in such cases, relatively uncommon though they are, that the clinical value of any special treatment can be most readily assessed. Moreover, it is in such cases which do not show the rapid and spontaneous recovery so typical of the ordinary jaundice case that some form of specific treatment is urgently required. The results obtained in such cases are best recorded by describing a typical example.

The patient was a young Canadian officer who was wounded in Italy in September 1943, transferred to North Africa for treatment and arrived in England in November. In December he developed a severe attack of infective hepatitis. Three months after the onset of the disease he was still icteric, in poor clinical condition and had lost 42 lb. in weight. Throughout this period he was anorexic, had frequent attacks of vomiting and was wasting steadily. In March 1944 he showed signs of an acute relapse and became gravely ill. He was transferred to one of our investigation wards for treatment. There was no suggestion of any cirrhotic change within the liver. Methionine was given intravenously in doses of 10 gm. on the first day he came under our care and on four subsequent occasions. After each infusion (indicated on the graph by an arrow), with the exception of the last which was given after the patient was obviously well and fit for discharge, the response was quite clear cut. Within twenty-four hours appetite improved and the liver receded, the serum bilirubin level fell sharply and four days later a marked gain in weight commenced (see graph). Occurring once, such a correlation between subjective symptoms, objective signs and therapeutic measures might well be coincidental. For this reason we withheld further methionine treatment until there was evidence of deterioration in his condition. It is probable that complete recovery would have been more rapid had methionine been given at shorter intervals. That recovery was eventually complete is suggested by the fact that a severe attack of hæmolytic streptococcal tonsillitis three weeks after discharge caused no apparent regression of his liver condition nor any rise in his serum bilirubin level. After discharge he continued to gain weight and reached his normal level within a few weeks.

We would make it clear that not all severely ill patients show such a gratifying response. Severe



cases may be broadly divided into three groups. In the first the illness is due to an apparently uncomplicated hepatitis. This may be long-standing, but is apparently unaccompanied by any marked degree of cirrhosis, and the response to methionine is good. In many chronic cases there is an acute hepatitis imposed on a pre-existing cirrhosis. Here there is a limited improvement the extent of which depends on the degree of cirrhotic change. A third group consists of those cases which have progressed to the stage of 'acute yellow atrophy'. The degree of hepatic autolysis is usually sufficient to produce a marked elevation of the blood amino nitrogen level. In such cases cellular destruction is so extensive that methionine is of no value.

## Simultaneous Determination of Aneurin and Nicotinamide Methochloride

Nicotinamide methochloride, the principal urinary derivative of nicotinamide, nicotinic acid and nikethamide, can be estimated in urine by adsorption on 'Decalso', elution with potassium chloride and extraction of the eluate with alkaline *iso*butanol[1]. By this procedure the methochloride is converted into a whitish fluorescent derivative, $F_2$, the concentration of which is estimated fluorimetrically. Aneurin is also estimated in urine by adsorption with 'Decalso', elution with potassium chloride and extraction of the eluate with *iso*butanol after the addition of alkali and potassium ferricyanide[2]. The thiochrome thus formed is estimated fluorimetrically in much the same manner as that employed for $F_2$. It has been found, however, that pure aqueous solutions of nicotinamide methochloride are also converted into a deep blue fluorescent pigment closely resembling thiochrome by alkaline-ferricyanide-*iso*-

butanol treatment[3]. In other words, the methochloride may be converted into the whitish fluorescent pigment $F_2$ by alkali and *iso*butanol alone, or into a deep blue fluorescent pigment by alkali, *iso*butanol and ferricyanide.

Both the methochloride and aneurin are present in normal urine. Alkaline ferricyanide treatment of either the untreated urine or potassium chloride eluates from 'Decalso' columns will result in the formation of a mixture of two bluish fluorescent substances. One of these is thiochrome, the other an oxidized derivative of nicotinamide methochloride $F_3$ (probably an N-methyl α pyridone derivative of nicotinamide).

No procedure so far elaborated has succeeded in separating these two pigments. A preliminary *iso*butanol washing of the urine is of no avail since the non-fluorescent methochloride is insoluble in *iso*butanol; nor is any adequate blank correction possible since alkaline *iso*butanol treatment of the urine or potassium chloride eluate without the addition of ferricyanide converts the methochloride into the whitish fluorescent pigment $F_2$.

Some of the procedures in use to-day for the estimation of thiochrome involve the subtraction of the fluorescence of the $F_2$ (blank) from the combined fluorescence of $F_3$ and thiochrome. This necessarily introduces an error in the assay since Najjar and Ketron's[3] observation that the fluorescence of $F_2$ is much greater than the fluorescence of the $F_3$ has been confirmed.

We have observed that if known amounts of the methochloride are adsorbed on 'Decalso', eluted with potassium chloride and treated with alkali, ferricyanide and *iso*butanol in the manner employed for aneurin assays, it is possible to determine the 'aneurin equivalent' of the $F_3$ formed by comparing it with the thiochrome standards used for the aneurin determination. By assaying the methochloride content of urine (alkaline *iso*butanol treatment of the eluate without the addition of ferricyanide) the fluorescence of the alkali-ferricyanide treated extract which is due to $F_3$ can be computed.

A procedure has been devised which makes it possible to estimate aneurin in the presence of nicotinamide methochloride and to estimate accurately the methochloride content by means of fluorescence standards in place of the usual commercial fluorimeters. The method is applicable to urine or extracts from foods. 1 gm. portions of 'Decalso' are washed into thistle funnels with an internal bore of 4 mm. The adsorbant is activated according to the procedure of Hennessy and Cerecedo. Urine or food extracts are adjusted to $p$H 4·0 and filtered through the columns; these are then washed with 20 ml. of 1 per cent acetic acid and eluted with 8 ml. of 25 per cent potassium chloride. Half of each eluate is treated successively with 0·25 ml. 0·5 per cent potassium ferricyanide, 1 ml. 20 per cent caustic soda and 5 ml. *iso*butanol and then shaken for one minute. The fluorescence intensity of this extract which contains the $F_3$ and thiochrome is compared with thiochrome standards prepared from aneurin solutions treated in the same manner. 1 ml. caustic soda and 5 ml. *iso*butanol are added to the other half of the eluate which is also shaken for one minute and compared with $F_2$ standards prepared from pure nicotinamide methochloride. The fluorescence due to the $F_3$ is computed from the methochloride assay and subtracted from the total blue fluorescence due to $F_3$ and thiochrome.

Certain precautions must be observed to ensure a fair degree of accuracy. The 'Decalso' obtainable in Great Britain will not completely adsorb aneurin or nicotinamide methochloride from concentrated urine if the volume is more than 10 ml., regardless of the care taken in activating the adsorbant. The urine should be diluted to a volume equivalent to an excretion of 150 ml. per hr., and if 1–10 ml. of this diluted sample is taken for assay the adsorption will be complete. The average values of the assays of three different volumes of urine should be taken. The potassium chloride eluates obtained in urine assays are invariably non-fluorescent, which indicates that no pre-formed thiochrome is present in untreated urine. Although a great many highly fluorescent pigments are present in urine, they are either not adsorbed on 'Decalso', or if they are adsorbed they are not eluted with potassium chloride and therefore they do not interfere with the assay.

It has not been possible to estimate aneurin by this method with a consistent error of less than $\pm$ 10 per cent. The addition of large amounts of both aneurin and the methochloride to urine containing known amounts of these substances and the subsequent assay of the mixture have given good results. It is felt that some workers have claimed too high a degree of accuracy for the thiochrome method in the assay of natural products since different laboratories using the same method in the assay of identical samples have not obtained a high degree of concordance[4]. Our method gives reliable and reproducible values in the nicotinamide methochloride estimation, which show an error of $\pm$ 5 per cent. The precautions suggested by Wang and Harris[5] and others for the development of fluorescence in the aneurin assay must be observed. The fluorescence of the reagents used must also be rigidly controlled.

In view of the great dissimilarity of chemical constitution, it is surprising that the $F_3$ derivative of nicotinamide methochloride and thiochrome are so similar in fluorescent properties and chemical stability. The fluorescence of both can be decreased or completely destroyed by the addition of strong oxidizing or reducing agents, exposure to light or by strong alkali. For most urines the addition of 0·25 ml. 0·5 per cent potassium ferricyanide is sufficient to convert the methochloride into $F_3$ and the aneurin into thiochrome. The assay of urines from subjects who have ingested large amounts of aneurin or nicotinamide or both is best accomplished by the dilution of the urines. It is unwise to add more than 0·25 ml. of ferricyanide without first calibrating the amount needed for the oxidation.

The presence of nicotinamide methochloride in meat, liver and milk of animals which methylate nicotinamide has been detected; the methochloride appears to be absent from cereals. An assay of a complete diet, if one assumes complete extraction of the methochloride by the methods recommended for the aneurin extraction, has shown that the total intake of the methochloride is about 7 mgm. a day. This concentration is sufficient to cause an appreciable error in the aneurin assay if no correction is made for the presence of $F_3$. It would seem that the assay of nicotinic acid in animal products gives results which are too high, since the alkali hydrolysed extracts of the physiologically inactive methochloride give a positive cyanogen bromide reaction. The methochloride does not seem to promote the growth of *Lactobacillus arabinosis*[6]. Whether it is active for

other micro-organisms used for vitamin assay is not determined.

This work forms part of an investigation on nutritional deficiencies carried out on behalf of the Air Ministry under the direction of Wing-Cmdr. T. F. Macrae; the author is a member of the Civilian Technical Corps.

## Determination of Aneurin by the Thiochrome Method after its Uptake by Yeast

FOR the determination of aneurin there are both chemical and biological methods. Among the former the thiochrome method is the most outstanding[1]. The biological methods are very tedious, and the error involved is considerable. For routine analysis, which necessitates the rapid attainment of a reliable result, the thiochrome method is the only one at present available. It involves the oxidation of the aneurin in alkaline solution to the fluorescent substance thiochrome, the latter being extracted with *iso*butanol or amyl alcohol and determined in a fluorimeter. The aneurin often occurs to a large extent as phosphate esters, for example, cocarboxylase, the thiochrome derivatives of which are not soluble in *iso*butanol. The thiochrome method gives excellent results with pure aneurin solutions or, for example, extracts of compressed yeast. In the determination of aneurin in certain materials, however, such as cereal products (especially flours of high extraction, bran, etc.), urine, blood, milk or molasses, complications arise, since interfering substances are present which in the oxidized or unoxidized state have different fluorescent powers, or influence the oxidation of the aneurin itself to thiochrome. A number of modifications have already been described, which, however, to judge from the literature, are not altogether satisfactory.

These difficulties have been overcome by the following method which is based on the previous work of Sperber and Renvall[2] and Sperber[3], who have shown that aneurin is very readily taken up by baker's yeast, especially under aerobic conditions and in the presence of a substrate. It has been found in these investigations and in those of Westenbrink and co-workers[4] that the aneurin in yeast occurs almost exclusively as pyrophosphate ester (cocarboxylase). This, however, is split up when the yeast is boiled; consequently the aneurin in the boiled extract is principally in the free form. Our procedure consists in shaking the material the aneurin content of which is to be estimated with baker's yeast, and afterwards determining the aneurin content of the extract obtained by boiling the yeast. Interfering factors present in the substance do not pass into the yeast extract.

Our investigations have shown that the capacity of the yeast for taking up aneurin is very great. Under the conditions of our experiments 1 gm. of yeast took up 900–1,000 μgm. aneurin from flour extract in the course of one hour's shaking. The quantities of yeast necessary are therefore so small that allowance generally can be made for the aneurin content of the yeast itself by means of an average value (in our case c. 4·5 μgm./gm.). In general we shook 50–200 ml. flour extract, containing about 60–120 μgm. aneurin, for ninety minutes at 25° C. (water thermostat) in Fernbach flasks with 2 gm. compressed yeast. In the beginning our results proved to be too low, despite the fact that, after shaking, the substance no longer contained any aneurin. The explanation must be that the phosphatase, which during the heating of the yeast splits up the cocarboxylase and other phosphate esters to aneurin (see above), had been inactivated during the shaking.

In this connexion reference may be made to the investigations on the pyruvic acid metabolism in starved yeast and aerated yeast performed by Runnström and co-workers[5]. The metabolism of pyruvic acid added to a yeast suspension is strongly inhibited in such yeasts. The results of this work, which is to be resumed, made it probable that it is the decarboxylation of the pyruvic acid through the agency of the cocarboxylase that is affected by the starvation or aeration treatment. It is possible that in this case also the above-mentioned dephosphorylation of the cocarboxylase plays a decisive part.

Attempts to use 'Diastase Merck', which, according to Ritsert[6], contains sufficient phosphatase to split the cocarboxylase, gave results which were not fully satisfactory. When this method is employed, the yield of thiochrome from the oxidation of the aneurin is diminished. The procedure is, moreover, rather lengthy. We therefore tried to employ the phosphatase of the yeast, adding fresh yeast to the shaken material. This proved to be without effect. It proved possible, however, to dephosphorylate the cocarboxylase in the shaken yeast by adding cytolysed yeast to the previously boiled extract of the shaken yeast and reboiling. Repeated analyses of the same flour gave values with a standard deviation of 2·6 per cent.

Aneurin added to flour extract was recovered, and in the determination of a cocarboxylase preparation values were obtained which corresponded well with the results of Warburg determinations on the same material. The method of analysis described is also used for the estimation of aneurin in molasses and urine.

A detailed account of these investigations will be published elsewhere.

## Configuration and Antiplasmodial Activity

THE current view[1,2] that there is no relationship between optical activity (configuration) and antiplasmodial action in the Cinchona series does not appear to be fully justified.

Neither the configuration of the asymmetric centres at $C_3$ and $C_4$[3] nor the bridged structure of the quinuclidine skeleton in quinine[1] has an influence on its activity. This latter statement follows from the fact that niquine and niquidine are biologically active[2] and that the same is true of the (6-methoxy-quinolyl-4)-α-piperidyl-carbinol (II) of Ainley and King[4]. The part of the molecule which is crucial for our discussion is, therefore, $C_8$ and $C_9$.

Furthermore, the *l*-alkaloids (with respect to both $C_8$ and $C_9$) are, at least frequently, not significantly different in activity from *d*-bases. The quinine equivalents are for:

| | | | |
|---|---|---|---|
| *d-apo*-quinidine methyl ether | 1·0 | *l-α-iso*-quinine | 0·6 |
| niquidine | 1·5 | niquine | 0·9 |
| dihydro-niquidine | 1·1 | dihydro-niquine | 0·6 |
| dihydro-cupreine | 0·9 | dihydro-cupreidine | 0·7 |
| dihydro-quinine | 1·35 | dihydro-quinidine | 0·8 |
| *apo*-quinine | 1·0 | *apo*-quinidine | 0·4 |

Epimerization at $C_9$ alone, however, causes complete loss of activity[5], whatever the configuration of the active compound epimerized is. One is, therefore, led to the hypothesis that alkaloids with the same sign of partial rotation at $C_8$ and $C_9$ have antiplasmodial activity; those with different sign of rotation at these two centres are inactive[2,6].

The following two conclusions which can be drawn from these considerations appear to be borne out by experiment.

(*a*) The quinine equivalents of optical antipodes (with respect to $C_8$ and $C_9$ only) do not differ more than by a factor of 1·5–2. Examples:

| | |
|---|---|
| Quinine | Quinidine |
| dihydro-cupreine | dihydro-cupreidine |
| *epi*-$C_9$-dihydro-quinine | *epi*-$C_9$-dihydro-quinidine |
| *epi*-$C_9$-quinine | *epi*-$C_9$-quinidine, etc. |

(*b*) The quinine equivalents of diastereomerides (with respect to $C_8$ and $C_9$ only) differ by a factor of 5–10. Examples:

| Alkaloid | Rotation at ($C_3$ + $C_4$) | $C_8$ | $C_9$ | Quinine equivalent |
|---|---|---|---|---|
| (1) Quinine | + | — | — | 1·0 |
| (2) *epi*-$C_9$-quinine | + | — | + | 0·1 |
| (3) Quinidine | + | + | + | 0·5 |
| (4) *epi*-$C_9$-quinidine | + | + | — | 0·1 |

(The pairs 1–2, 3–4, 1–4 and 2–3 are also diastereomerides.)

In view of these data, it is significant that the two isomers of Ainley and King's substance (II) have rather different antiplasmodial activity (the isomer of m.p. 162–163° about the same as quinine, that of m.p. 187–188° only 25 per cent of it). As, according to the synthesis, the two substances are diastereomides, one is tempted to suggest that the signs of rotation at the two asymmetric carbon atoms (which correspond to $C_8$ and $C_9$ in the quinine formula) are the same in the more active isomer of m.p. 162–163° and are different in the less active isomer of m.p. 187–188°. (Both of them are, of course, racemates.)

The somewhat unusual regularities which emerge from the accumulated experimental material seem to suggest that—in contradistinction with so many other biological effects—an optically active selective chemoceptor[7] is not responsible for antiplasmodial activity.

## Antibiotic Action of *Aspergillus fumigatus* against *Mycobacterium tuberculosis*

MANY papers have been published on the antagonism of certain micro-organisms against acid-fast bacteria, particularly *Mycobacterium tuberculosis*[1,2,3,4], recording varying results. I have tested during the past year various fungi for antagonism to acid-fast bacteria and have found *Aspergillus fumigatus* No. 367 of the National Collection of Type Culture to be the most effective.

Of the different media tested, Czapek-Dox medium with 2 per cent tryptone, 4 per cent brown sugar and 5 per cent glycerine yielded the best results. The active filtrate will be referred to as 'aspergillin'. The antibacterial power of the culture, which reaches its maximum in about 15–20 days, was determined by making serial dilutions of aspergillin in fresh broth with 5 per cent glycerine contained in 50 c.c. conical flasks, or 2-oz. flat medicine bottles. Then these were inoculated with a small amount (1–2 mgm.) of a young culture of acid-fast bacteria on glycerol broth or egg medium. In each test control cultures were also seeded. The cultures were incubated at 37° C.

The degree of growth in the various dilutions of aspergillin was compared with the growth on the control cultures at intervals of time. The final examinations of the cultures were made after 4–6 weeks in the case of *Mycobacterium tuberculosis* bovine and human type, with *Mycobacterium tuberculosis* avian type and *Mycobacterium phlei* after six days. For

the routine testing of activity *Mycobacterium phlei* was employed. *Mycobacterium tuberculosis* bovine, human and avian types were inhibited in the media containing 5–10 per cent, *Mycobacterium phlei* in the media containing 1–2 per cent of aspergillin. Two strains of Staphylococci tested were not inhibited. Judging from sub-culture tests, aspergillin seems to be bacteriostatic rather than bactericidal. It is not toxic to experimental animals in large doses and boiling for one hour does not destroy it. The next step is to purify this substance and then to test it as a chemotherapeutic drug against *Mycobacterium tuberculosis*, and to establish the possible relation or difference in the chemical and biological nature of other substances produced by *Aspergillus fumigatus*.

My thanks are due to Mr. C. A. McGaughey, acting director of this Institute, for laboratory facilities and his keen interest in the work and to Mr. M. O. J. McCarthy for the test of toxicity in the animals.

## A Powerful Inhibitory Substance produced by Group *N* Streptococci

IN 1933[1] Whitehead and Riddet, in New Zealand, observed that bulk milk stored overnight in cheese factories sometimes inhibited the growth of the 'starter' culture added to develop the acidity necessary for the cheese-making process.

From the stored milk Whitehead isolated a streptococcus and showed that it produced an inhibitory substance which he considered to be of protein or polypeptide nature[2]. Similar strains have been isolated from milk and starter by others[3,4], and those we have used in our work have been found to fall into Group *N*[5]. The inhibitory substance appeared to be powerful and it occurred to one of us that pathogenic organisms, in particular Group *B* streptococci causing bovine mastitis, might be similarly inhibited.

We have found that many groups of pathogenic streptococci are in fact inhibited even in media containing high proportions of serum or blood. Some species of Bacillus, Clostridium and Lactobacilli are also inhibited but staphylococci so far tested are less susceptible. All Gram-negative organisms so far tested were unaffected.

Since the substance proved to have marked inhibitory properties *in vitro*, preliminary attempts to concentrate it by chemical means were made. A product of high potency was obtained and a serial dilution technique used to assay it.

It completely inhibited the growth of the test organism (*Str. agalactiæ*) in a dilution of 1/640,000, and partial inhibition was observed at 1/1,000,000. The percentage of active substance in this product is, we know, small, so that these dilutions underestimate the activity of the prime inhibitory substance.

Using this impure material in a small preliminary mouse protection experiment, it was found that a single intravenous dose of 2 mgm. following inoculation with about 1,000 lethal doses of a mouse virulent hæmolytic streptococcus had marked therapeutic properties.

A further experiment using twenty control and twenty treated mice was therefore carried out. Each mouse in each group received about 10,000 lethal doses of the streptococcus used in the preliminary experiment, the virulence of which had been raised by animal passage. The untreated control group all died within twenty-four hours. Each mouse in the treated group received, subcutaneously, a total weight of 10 mgm. of the inhibitory substance in three-hourly doses spread over forty-five hours. All the animals were alive and active at the end of this time, when treatment ceased. At the end of seven days from the beginning of the treatment 40 per cent were apparently completely cured. Little or no local or general reaction was observed and toxicity tests with guinea pigs receiving 10 mgm. of the substance in a single dose were completely negative.

The product appears to have certain properties desirable in an inhibitory substance of biological origin. The crude preparation, at least, is heat-stable. The substance is produced in a simple broth medium, and pure culture on a large scale is not difficult. Strains of high potency are easy to select and appear to be stable for months at least.

Even the crude substance is well tolerated on subcutaneous and intravenous injection in distilled water solution. It is dialysable and is therefore a comparatively small molecule. Experiments in purification and application are continuing.

## A Case of Choline Poisoning in Cattle

IN cattle at Kiriat Anavim (Palestine) the following pathological symptoms were observed. After the first calving the uterus did not contract but remained open and atonic for a considerable time, thus forming a source of secondary infections. This condition, which could not be influenced by the usual medical treatment, resulted frequently in inability to conceive and in abortions. No primary infectious disease could be found nor did anatomical or histological examinations of the sexual organs yield any result. The foodstuffs given were the same as employed usually in Palestine dairy farming. They were not deficient in nutrients, minerals and vitamins. The only unusual foodstuffs given were wet brewer's grains, which formed a considerable part of the rations for some years. Infected barley is known to have had detrimental effects in some cases, owing to an excessive content of amines[1], especially free choline[2]. Since normal barley generally does not contain appreciable amounts of free choline, we undertook to compare the brewer's grains with normal barley in respect to their choline contents.

The choline was obtained by extracting the materials with 60 per cent alcohol, and, after evaporation of the alcohol, removing the proteins, salts and other

impurities and precipitating the choline as the $HgCl_2$ compound. The choline was determined quantitatively as the reineckate[3]. Analyses of the $HgCl_2$ compound and of the reineckate confirmed the identity of choline. The amounts extracted were 20·0 kgm. fresh brewer's grains (containing 22 per cent dry matter) and 2 kgm. dry barley. Brewer's grains yielded 0·25–0·28 per cent choline (calculated as dry matter), whereas normal barley contained *no free choline*. A yield of 0·17 per cent choline was obtained only after saponification with barium hydroxide.

These findings seem to justify the conclusion that free choline can act as a poisoning agent when fed over long periods of time.

## A Possible Gene Duplication in New Zealand Romney Sheep

THE mode of inheritance in New Zealand Romneys of the N-type birthcoat, in which there is very high abundance of halo-hairs on the main area of the body, has been shown to be simple in three stocks of sheep[1,2]. In two stocks of independent origin N-type is a simple dominant to non-N. In the third, which is related to one of the dominant stocks through a common ancestor, the breeding experiments of the last two seasons have given further proof that N-type is a simple recessive to non-N. In addition, a small inbred N-type flock in which the mode of inheritance is multifactorial has been gradually but rapidly built up by selection.

Nearly all N-type rams, of whatever stock, are horned. It was formerly thought that in dominant-N sheep horns were conditioned by a sex-influenced factor linked with the factor for N-type with about 10 per cent crossing-over. It is now better to regard horns as a usual expression in males of any genetic make-up which gives an N-type birthcoat. In females the breeding results point to homozygous dominant-N animals ordinarily having horns, which are much smaller than most rams' horns. Occasional heterozygous dominant-N ewes are horned or have scurs or buttons, the latter being hard projections which do not pierce the skin. Recessive-N ewes have so far all been polled. So have most multifactorial-N ewes, but a few have horns, and several have scurs or buttons.

The central problem in genetic analysis is the relation between dominant-N and recessive-N. In developing earlier ideas, as two more crops of lambs have been born, emphasis is put the more on duplication, and it no longer seems helpful to think in terms of a dominigene or a suppressing factor. The present hypothesis is simply that the dominant factor for N-type is a duplication of the recessive gene for N-type. There is a substantial chance that in the experimental stocks the recessive gene has been duplicated on one or more occasions, and that the supposed dominant duplication has, once or a few times, been halved to give a germ cell possessing the recessive gene. The grounds for thinking that these things happen are not yet conclusive, and the main purpose of the breeding experiments has become to test the hypothesis that has been stated. We must ascertain whether dominant-N, non-N and recessive-N are multiple alleles, and must give more lambs suggestive of unequal crossing-over or the halving of a duplication the chance to be born.

If such crossing-over does indeed take place the data suggest its frequency to be nearer 1 in 100 than 1 in 10 to any other power. For an event that one thinks of as a rare abnormality this frequency seems high, but that it can happen so often is believable in the light of Drosophila work[3,4,5]. If a duplication were advantageous to the live-stock breeder, and took place with a frequency of this order, it would be worth while for him to watch for it. Moreover, the recent work on Drosophila, following the discovery that 'bar' is a duplication, suggests that this phenomenon is more than an out-of-the-way oddity. In the mouse, too, duplication may well be involved in the work of Dunn and Caspari[6]. Without the Drosophila work the present hypothesis seeking to explain sheep-breeding results would assuredly not have been put forward. Problems of selection in slow-breeding animals being so difficult, it is tempting to speculate on the possible significance for live-stock breeding of the duplication of a gene which thereby becomes in some way more powerful.

## The Commutation of Annual Subscriptions

I WAS interested in Dr. David Heron's letter in *Nature* of September 23, p. 400. The Royal Aeronautical Society allows compounding of annual subscriptions after payment of the entrance fee and first annual subscription, as follows: fellows, 12 years subscriptions; associate fellows and other grades, 15 years subscriptions. The amounts are reduced by one guinea a year for each year of membership after five years. The minimum ages for fellows is twenty-eight and associate fellows twenty-five. An additional compounding fee is payable on transference from associate fellow to fellow if the former has already compounded his subscriptions, on a *pro rata* basis of annual subscriptions. The whole of the entrance fees and life compositions are invested in an endowment fund, the interest only of which is available to the Society's funds. It will be noticed that the composition fee is irrespective of age. An associate fellow elected at twenty-five can compound for fifteen years subscription, while one elected at thirty-five will still have to pay the same composition fee. The fees were adopted on the advice of the Society's honorary accountant.

# RESEARCH ITEMS

## Management of Small Artificial Lakes

GEORGE W. BENNETT gives a "Summary of Fisheries Investigations, 1938–1942" on this subject (*Bull. Illinois Nat. Hist. Surv.*, 22; 1943). The primary objective of fish management is to produce and maintain good fishing. The author defines 'good fishing' as including the element of numbers of fish caught for unit of time or effort, as well as that of size of individual fish. There is much to be done in maintaining these small artificial lakes, and this report gives a valuable summary of researches. The best fishes for these Illinois artificial lakes are large-mouth bass *Huro salmoides*, white and black crappies *Pomoxis nigro-maculatus*, bluegills *Lepomis macrochirus* and black and yellow bullheads *Ameiurus natalis natalis*. Other fish are apparently of little value in hook-and-line fishing. The chief causes for poor fishing are past improper stocking, large population of rough fish or other fishes of little use for angling, and stunting as a result of over-population. Lakes should be cropped in order to produce and maintain good yields. A cropping plan should include measures to control the numbers of fish of small size as well as the total poundage of large fish taken by anglers. Simple combinations of fishes tested to determine their value for angling shows the bass-bluegill combination to be one of the most satisfactory.

## Individual Variability of Micro-organisms

INTENSIVE studies in the polymorphism of cells of *Saccharomyces cerevisiæ*, carried out for 70–80 successive generations by N. A. Krasilnikov (*J. Gen. Biol.*, Moscow, 4; 1943), suggested a definite connexion between the individual variation and the formation of stable strains. It was established that the individual characters of each variation type are transmitted to the progeny, but with unequal degrees of persistency. In some cases, certain characters may persist through tens, and even hundreds, of generations; in others they do not extend beyond the third generation; and sometimes such individual characters are not inherited at all. Polymorphism tends to increase with the age of a culture and individual variants gradually become stabilized. The new strains formed in this manner are not reversible, but their eventual fate in the culture depends on the outcome of the competition with the initial strains from which they had split off; this fate is influenced by the nutrient medium being more favourable to one of the competing strains.

## The Tetrapod Middle Ear

THE study of new material of the hyomandibular and its relationships to the auditory and occipital regions of the skull in *Eusthenopteron*, a member of the rhipidostian crossopterygian fishes, has enabled T. S. Westoll (*Trans. Roy. Soc.*, B, 131; 1943) to give a more complete and accurate account than was furnished previously by Sternberg, who had only badly crushed material at his disposal. With this as a basis, Westoll proceeds to examine the general question of the tetrapod middle ear. The hyomandibular, he agrees, in conformity with a theory that has been suggested previously, becomes transformed into the stapes and its processus opercularis becomes the extracolumella. The development of a freely movable neck articulation early in the tetrapod stock resulted in considerable modifications of the hyobranchial apparatus, and further changes ensued with the transfer of the bones at the posterior end of the lower jaw in the reptiles. The homology of the tympanic cavity and membrane throughout the series has been denied by some authorities; but the author holds that from a primitive, dorsally situated tympanic diverticulum exemplified in the anuran amphibia arose a ventral, infra-stapedial recess in many reptiles and a further, more ventral mandibular recess in the theromorph reptiles, so that the whole form a homologous series the primitive parts of which are reduced in the mammals.

## Carbon Dioxide Metabolism in Insects

ACCORDING to current views, the blood of insects has no respiratory function, gaseous metabolism being carried out through the tracheal system, the organism getting rid of carbon dioxide not only directly through the tracheæ but also by the diffusion of carbon dioxide through the tissues. Under these conditions, any tendency of carbon dioxide to hydration, that is, to conversion into $H_2CO_3$ and $HCO_3$, would be hampering the elimination of carbon dioxide from the organism. Investigations by Kreps and Chenikayeva on the blood of orthopterous insects (*Bull Acad. Sci. U.R.S.S.*, No. 5; 1942) have shown that no carbonic anhydrase could be detected in it. In fact, it was discovered that the blood has a pronounced inhibitory effect on the hydration reaction of carbon dioxide. The inhibition factor contained in the blood is thermostable, withstands intensive boiling, is insensitive to poisons (for example, cyanide, sodium azide, etc.), prevents enzyme action, and is not bound to proteins. It is suggested that the inhibitor is not an enzyme. The biological significance of the inhibitor consists, presumably, in preventing hydration of the highly diffusible carbon dioxide to the slowly diffusible $H_2CO_3$ and $HCO_3$. The inhibitor, therefore, appears to form an essential feature of tracheal respiration.

## Pairing of Sex Chromosomes

GENETIC crossing-over between the sex chromosomes in the male of *Drosophila pseudoobscura* is rare or probably does not occur, yet these chromosomes are conjoined over part of their length during the diakinesis-anaphase period of meiosis; conversely, autosomes pair normally and genetic crossing-over occurs. In Darlington's chiasma hypothesis of metaphase pairing, chiasmata provide the primary, if not only, means of conjunction of chromosomes as bivalents. It is therefore assumed that the sex chromosomes in the male of *Drosophila pseudoobscura* are held together by chiasmata which are reciprocal and confined to inert regions of the chromosomes. K. W. Cooper has followed meiosis in the male of another fly, *Olfersia bisulcata*, which shows apparently similar phenomena (*Proc. U.S. Nat. Acad. Sci.*, 30, 50; 1944). In this type the sex chromosomes of the male do not pair until after condensation and then form the *X–Y* bivalent by means of approximation of localized pairing segments, which presumably do not form chiasmata. From observations by Darlington on *Drosophila pseudoobscura* it seems not improbable that here also the *X–Y* bivalents may be the result of late pairing during or after condensation. Such cases of delayed pairing are not unique among

insects. The full significance of the observation is not clear but suggests that bivalent formation in *Drosophila pseudoobscura* would repay closer analysis and that the chiasma hypothesis of metaphase pairing may not be capable of covering all the facts.

### Incompatibility in Tetraploid Clover

RECENT papers have given evidence of peculiar reactions of the incompatibility factors causing self- and cross-fertility in polyploids as compared with diploids. S. S. Atwood (*Proc. U.S. Nat. Acad. Sci.*, **30**, 69; 1944) has confirmed the behaviour of diploid and tetraploid clones of *Trifolium repens* in this respect. Two diploid plants, $S_1S_2$ and $S_3S_4$, gave rise after colchicine treatment to tetraploids. These tetraploids were self-incompatible, thus differing from results in *Petunia violacea* and *Oenothera organensis*. $F_1$ from the tetraploids were obtained with differing genotypes. By backcrossing and reciprocal crossing, the author shows that when only one type of heterozygous pollen is produced the presence of one or both factors in the style will inhibit growth; and that when several types of heterozygous pollen are produced none is inhibited in the pistil although there may be a similar factor in the style. It seems apparent that sometimes pollen growth depends on the total interaction of the pollen and style and not on a specific oppositional effect between one type of pollen and the style. Further evidence of this nature would be valuable in shedding light on the mechanism of inhibition of pollen tube growth.

### Hornlessness in Goats

S. A. ASDELL (*Science*, **99**; Feb. 11, 1944) suggests that the craze for selecting hornless goats has increased the percentage of intersexual animals. He has examined about three hundred animals which were intersexual and found that in every case they were hornless. He believes that intersexual goats are all females modified by a recessive gene which may be closely linked with hornlessness.

### Contamination of Porcelain Insulators

ACCORDING to W. G. Thompson (*J. Inst. Elec. Eng.*, **91**, Pt. 2, No. 22; August 1944) in a paper on the mechanism of contamination, an analysis of the nature of the air-borne particles forming the main source of contamination on outdoor porcelain insulators, and of the forces acting upon them in the electrostatic field around an insulator, suggests that these forces are inadequate to account completely for the observed distribution and the quantity of the deposits. Direct measurements of the field-strengths close to the insulator confirm that the voltage gradients do not reach very high values in normal conditions, and that the electrical forces are proportionately weak. Investigations of the air flow over the insulators, and comparisons of the formations of air eddies observed in the flow over the geometrical forms associated with the complex shapes of insulators, show that the aerodynamic conditions have a considerable bearing upon the patterns formed by the deposits on the insulators. Wind-tunnel experiments provide results which illustrate the influence of the Reynolds' number, the applied voltage, the surface roughness, the wind velocity and the humidity upon the distribution and amount of deposited matter. Moisture films constitute a special case of temporary contamination, with sparking following the receding edges of the drying films. Finally, a method is suggested of estimating the flashover values of insulators from a consideration of the distribution of surface resistance as modified by the presence of deposited matter. In the final determination of insulator performance from the anti-dirt point of view, it is essential to have recourse to the test racks of the testing stations and the manufacturers' laboratories, and to supplement the evidence obtained by service experience on overhead lines. The complete account must involve a study of the means by which material deposited on insulators is removed by wind, rain and frost, but there seems little object in attempting a study of this nature using only artificial deposits.

### Continuous Absorption Coefficient of the Negative Hydrogen Ion

RECENT attempts to find the source of the continuous opacity in stellar atmospheres, though they have strongly suggested that the negative hydrogen ion is responsible for much of the absorption, have resulted in only qualitative agreement between theory and observation. The quantitative breakdown of the theory in the visual region of the spectrum was traced a year ago by Chandrasekhar and Krogdahl to the use of a wave function of the ground-state of $H^-$ which was not sufficiently accurate at distances of the order of five times the Bohr radius. Henrich has now computed new absorption coefficients (*Astrophys. J.*, **99**, 59; 1944) using an eleventh-order Hylleraas type of wave function (third- and sixth-order functions had been used previously), and finds that the absorption reaches a maximum at 7500 A., which is 30 per cent higher than the previous maximum, which occurred at 4750 A. This modification considerably reduces the discrepancy between theory and observation in the relation between effective temperature and colour temperature in the visual region of stellar spectra, and establishes on a firm basis the hypothesis that the negative hydrogen ion is an important contributor to opacity in stellar atmospheres.

### Perturbations of Plato

IN *Observatorio Astronómico De La Universidad Nacional De La Plata*, **17**, 1941, Reynaldo P. Cesco, has a paper with the title "Perturbaciones Seculares De Plutón". Owing to the close approach of the orbits of Pluto and Neptune, difficulties arise about the application of the Gaussian method which, in such circumstances, is unsatisfactory. The author attacks the problem by developing $1/\Delta$ in powers of $e$, $e'$, and $\eta^2$, in a manner similar to the Laplace-Le Verrier method, but amplified by the use of certain corrections developed by Boquet. It is shown that the series converges even under the most unfavourable conditions for the two planets under consideration. The second chapter gives the formulæ for computing the coefficients and their derivatives, first for a definite value of the mutual inclination of the orbits, and then for the general case. In Chapter 3, reverting to the representation of the perturbative function and its derivatives by double integrals, by means of a convenient application of the theory of approximations by polynomials, a method for computing secular perturbations is developed. This method is sufficiently accurate, at least in the first approximation with respect to the mass. It is very suitable for Pluto and Neptune and its application to these planets is shown in Chapter 4.

# RADIO AND ELECTRICAL ENGINEERS

THE application of electricity to signalling along wires in the latter half of the nineteenth century led to the foundation in 1871 of the Society of Telegraph Engineers. At a later date the title was changed to the Institution of Electrical Engineers and its scope expanded to enable it to cater for the interests of all those professionally engaged in electrical engineering in Great Britain. Moving with the growth and development of wireless telegraphy and telephony, the Institution inaugurated in 1919 a Wireless Section to deal with the subjects of high-frequency engineering and audio-frequency recording and reproduction. Shortly afterwards, the Institution was incorporated by Royal Charter, and the fully qualified members were granted the right to describe themselves as chartered electrical engineers. At the same time, it was recognized that, while maintaining the standard of the qualifications for membership, more opportunity should be afforded to the physicist engaged in radio work to become a member. It is particularly opportune to direct attention to this fact at the present time, when a large number of men engaged in scientific and technical radio work would probably describe themselves as radio physicists rather than as wireless or radio engineers. The Institution thus welcomes as potential members those who, although not having received the usual training of electrical engineers, nevertheless hold degrees or equivalent qualifications in physics and are fully expert in their own branch of radio technique. It is perhaps significant of the times to point out that for the past three years the president of the Institution of Electrical Engineers has been a member whose main professional interest has been in the field of telecommunications, the present holder of that office being Sir A. Stanley Angwin, engineer-in-chief of the Post Office.

On May 3 last, the Wireless Section of the Institution held a special meeting to commemorate the silver jubilee of its formation in 1919, and six past chairmen of the Section delivered short addresses which have now been published (*J. Inst. Elect. Eng.*, 91, Part III, No. 15, September 1944). After an introductory address by the president, Dr. W. H. Eccles gave a short account of the technical events in the early progress of wireless communication which led to the formation of the Wireless Section. Prof. G. W. O. Howe followed with a survey of the development of the principles and theory of the subject, with special reference to the properties of the ionosphere. The early development of wireless telegraphy in the Navy from 1899 onwards was dealt with by Admiral Sir Charles E. Kennedy-Purvis, who referred to the fact that the close co-operation between the Navy and the General Post Office has from the beginning been a characteristic feature in wireless progress in Britain. The life of the Wireless Section of the Institution of Electrical Engineers has coincided with the growth of practical wireless telephony, for it was in 1919 that the early experiments in the transmission of speech and music took place in Great Britain and paved the way for the development of broadcasting. Starting from this point, Mr. H. Bishop traced the history of the British Broadcasting Corporation and its activities in providing a British and Empire broadcasting service. He also referred to the growth of television, in which field, prior to the present War, Great Britain held a decisive lead over all others, including the United States of America. Finally, Dr. R. L. Smith-Rose attempted to portray what the future might have in store when the greatly increased knowledge and experience gained during the War becomes available for application to peace-time requirements. The whole field of radio communication and navigation, and of aural and visual broadcasting would make rapid and important advances; and Dr. Smith-Rose looked forward to the day when radio-controlled pilotless freight-carrying aircraft would fly distances comparable with that of the North Atlantic route between Great Britain and North America. Reference was also made to the heavy debt which all the applications and advances that were mentioned by the various speakers at the meeting owe to those patient investigators and research workers, who in recent years have laid the foundations and established the essential facts which form the basis of all development work.

Since the jubilee meeting just referred to, the Council of the Institution of Electrical Engineers has decided to change the name of the Section from "Wireless" to "Radio", and to extend its scope to cover the field generally known nowadays as "electronics". In this way the Institution has shown itself fully alive to the progress of the art and science of radio technique, and to the necessity of keeping this Section virile and up-to-date, and capable of representing the best interests of those engaged in the radio profession.

The chairman of this Radio Section for the current year is Mr. H. L. Kirke, head of the Research Department of the B.B.C.; and on October 11 he delivered his inaugural address to the Section, the members of which now number about two thousand. In the first portion of his address, Mr. Kirke referred to the fact that it has been felt for some time that there ought to be closer co-operation with the Institute of Radio Engineers of America. War conditions made a definite move rather difficult, and it was clear that the matter needed oral discussion. An opportunity for this occurred early this year, when both Mr. Kirke and Dr. Smith-Rose, a past chairman of the Radio Section, were in the United States; they were invited, together with Mr. F. S. Barton, also a member of the Section and recently a vice-president of the American body, to attend a meeting of the Board of Directors of the Institute of Radio Engineers in New York. At this meeting a number of proposals were discussed and very well received; and in order to put these into effect, a special Liaison Committee has been formed in Great Britain to work with a similar committee in the United States. Thus a close link has been forged between the Radio Section of the Institution of Electrical Engineers in Great Britain and the Institute of Radio Engineers in the United States; and it is hoped that, as a result, there will be a freer interchange between the two bodies of papers, discussions and other matters of mutual interest.

In the second part of his address, Mr. Kirke dealt with the subject of impedance measurement at radio frequencies. There has been considerable development in this field over the past decade. Mr. Kirke described, with the aid of diagrams and photographs and an exhibition of the apparatus, five types of radio-frequency bridge which have been developed and used during the past ten years: reference was also made to the associated apparatus and to a low-

frequency capacitance bridge which was the forerunner of some of the radio-frequency equipment. Those interested in this type of apparatus technique will look forward to the publication of the address in the *Proceedings* of the Radio Section of the Institution.

## GEOLOGICAL SERVICE OF THE U.S.S.R.

THE Soviet Geological Service is working hard on problems connected with the defence of the country, the development of industry and the rehabilitation of the national economy of the liberated regions.

I. I. Malyshev, the chairman of the Geology Committee of the Council of People's Commissars, states that this year Soviet geologists are concentrating on a search for new mineral deposits. The Committee has already sent out more than six hundred parties of geologists and experts for field work.

Newer methods of work have been adopted, among which is the use of geophysical instruments which reveal the magnetic, gravitational, seismic and other features of rocks. The employment of these methods in past years has led to a number of discoveries being made. For example, an aeromagnetic survey of Western Siberia led to the discovery of new iron ore deposits.

This year's prospecting is mainly to find new deposits of molybdenum, tungsten, tin, mercury, mica, etc. Great importance is placed on these surveys as increased quantities of raw materials are needed for the iron and steel mills now being built in Siberia, Kazakhstan and other parts of the country.

It is hoped soon to complete the work on composite hydrogeological maps of the industrially and economically important regions of the U.S.S.R. These maps will show sub-soil waters, their quality, the conditions under which they are found, and the possibility of their being used for industry, transport, agriculture, and the water supply of inhabited centres. This information is valuable in planning the economic development of the districts concerned. In compiling these maps, data obtained by specially organized hydrogeological expeditions were added to the mass of available geological material. An example of the importance of the work done in the realm of hydrogeology is the discovery last year of deposits of fresh, sub-soil water at an accessible depth in the seemingly waterless Kara Kum desert.

All work and expeditions of this nature are under the direction of the All-Union Research Institute for Hydrogeology and Engineering Geology. The All-Union Commission on Mineral Deposits will this year confirm the estimate of coal supplies available to all enterprises in the coal-mining industry; and the same will be done for the oil industry.

The scope of the State Geological Survey has been increased by almost 50 per cent this year. The Survey will give a complete picture of the geological structure of the U.S.S.R. and provide the foundation for all future prospecting and survey work. Aerial photographs are extensively used for this work.

Another important institution is the All-Union Geological Records which collects material on all the geological work done on Soviet territory. This year it is compiling a sort of encyclopædia of all known mineral deposits of the U.S.S.R. which will run into about 16,000 printed pages.

Soviet geologists are also busy at the front. Special detachments of geologists are working on all sectors of the front providing geological data for the advancing Red Army.

They supply the staff with necessary information when the Red Army has to force water-courses, pointing out places through which tanks can pass, help in organizing the army's water supply, search for building materials for dug-outs, roads and bridges, and give advice regarding camouflage. This work is frequently carried out under enemy fire. The selfless work of many geologists at the front has been marked by the award of Government decorations.

## ECONOMY IN THE USE OF DRUGS

THE first edition of the Medical Research Council's War Memorandum No. 3, entitled "Economy in the Use of Drugs in War-time", was issued in March 1941. It represented the views of the Council's Therapeutic Requirements Committee and a first Supplement to it was issued in November 1941. A second revised edition is now issued (H.M. Stationery Office, 1944. 3*d*.). It includes an appendix on economy in the use of bactericides and disinfectants, large quantities of which are, the appendix says, used in hospitals and private practice under conditions in which they are not likely to be effective. Sterilization by heat is always preferable to the use of disinfectants and should be used if possible. Mercurial disinfectants have to be imported, and mercury is required for munitions, so that the indigenous coal-tar disinfectants should be used as much as possible. The same Council's War Memorandum No. 6 on "Prevention of 'Hospital Infection' of Wounds" contains recommendations for the use of disinfectants of the phenolic type.

An appendix to the first edition of the Memorandum described the production of drugs in the British Empire, but "the activities arising in this connection" have since been assumed by the Vegetable Drugs Committee set up by the Minister of Health. This Committee now works within the organization of the Ministry of Supply. Responsibility for the provision of drugs and therapeutic substances is now vested in the Ministry of Supply, which acts in consultation with the Ministry of Health, and both Ministries are represented on the Therapeutic Requirements Committee. Difficulties in obtaining supplies of important drugs should be referred to the Directorate of Medical Supplies, Ministry of Supply, Portland House, Tothill Street, London, S.W.1.

This second edition of the Memorandum revises and extends the lists given in the first edition. It adds many new items and incorporates the first Supplement. Further, the method of classifying the substances listed has been changed. In the first edition Class *A* brought together drugs which were regarded as essential and those which were readily available without indicating which of these reasons determined the inclusion of particular drugs in this Class. At the time of publication it was undesirable to publish this information. It has, however, become increasingly difficult to keep separate the ideas that a drug may be on one hand readily available and on the other essential. Too rigid a classification may defeat its own object unless there is a rigid scheme of rationing,

which has not yet been necessary. In any event no drug can be regarded to-day as being freely available, and economy is necessary in the use of all drugs. This second edition of the Memorandum has therefore classified substances into *A*, drugs which are important therapeutic agents and which should be made available so far as is possible; *B*, drugs which are needed for certain purposes, but supplies of them are limited—it is left to the good sense of the prescriber to use these only for purposes for which they are known to be valuable; alternatives to them are indicated, whenever this is possible; *C*, drugs which are not essential and do not justify importation or manufacture for home use in war-time. The list includes many substances which are used in chemical, biological and other laboratories, as well as those used by medical men and veterinarians.

## SUMMER SCHOOL IN X-RAY CRYSTALLOGRAPHY AT CAMBRIDGE

THE second Summer School of X-Ray Crystallography, held at Cambridge during September 4–15, was opened by Sir Lawrence Bragg, and the nineteen lectures, followed by sessions of practical work, were shared by Miss A. M. B. Parker and Drs. N. F. M. Henry, H. Lipson, D. P. Riley and W. A. Wooster. The organization and syllabus of the course were similar to those of last year (see *Nature*, Oct. 2, 1943, p. 381).

The application of X-rays to crystallographic problems of industrial importance has made dynamic advances, but remains a young science still largely cradled in the universities and similar academic laboratories. Many of the senior technical men attached to industrial organizations have had no opportunity of acquiring more than a superficial knowledge of the subject and its possibilities; while graduates just entering industry, though they may have received some training in X-ray methods, can scarcely be expected fully to appreciate their application to practical technology. A gap clearly exists which it was the purpose of the School in some measure to bridge; to quote the syllabus of the course, "the chief aim is to give scientists and technicians a training in the fundamentals of the subject, to bring them into touch with the wide range of methods used, to teach them the newest techniques, and to indicate the many types of industrial problems in which this work can be used with advantage". There is no doubt that these aims were admirably fulfilled.

Twenty-nine people assembled for the lectures, and as nearly half the number were concerned more or less directly with metals it is fitting that the course had a distinct bias, especially in its later and more practical part, towards the metallurgical field. During the first week attention was confined to the more fundamental aspects of the subject, dealing with the representation in projection of the symmetry and internal structure of crystals, the laws governing the 'reflexion' of X-rays from lattice planes and the several methods of taking and interpreting X-ray photographs of single crystals. In the second week, the knowledge so acquired was applied to the study of polycrystalline aggregates by means of 'back-reflexion' and 'powder' photographs, and the essentially practical nature of the course emerged. Familiarity was gained with such matters as the accurate determination of lattice spacings, the identification of crystalline substances and of the phases present in alloys; the assessment of preferred orientation, internal stress and grain-size in metals and the study of imperfect forms of crystals such as those occurring in rubber, textile fibres and plastics.

An important aspect of the more advanced work was the pains taken to point out the limitations of the methods at present available, and to indicate the probable lines of future progress. E. Voce.

## SPORE-FORMING BACTERIA PATHOGENIC TO PLANTS

IT is a curious fact that whereas the bacterial diseases of animals are due to many types including spore-formers, the large number of bacterial diseases of plants which have been carefully investigated are caused by bacteria which do not form spores. That some spore-forming bacteria of the *Bacillus subtilis* group can be pathogenic to plants has often been stated but never generally accepted by plant pathologists, either for lack of adequate proof or because of failure to obtain positive results on re-investigation.

There are, however, at least two accounts of experimental work which conform to the standards of rigid proof required in such work. Brierley (*Phytopath.*, 18, 819; 1928) presented good evidence to show that a bacterial rot of potato tubers was due to a spore-forming organism identified as a strain of *B. mesentericus*, and recently Madhok (*Indian J. Agric. Sci.*, 13, 129; 1943) has investigated a rot of tomato fruits due to a member of the same group and for which the name *B. fructodestruens* is proposed. A sticky bacterial rot of potato tubers is under investigation at Cambridge due to *B. polymyxa* which, according to Dowson (*Nature*, 152, 331; 1943), is pathogenic to a large number of plants including green tomato fruits when inoculated under laboratory conditions. Allen (*Nature*, 153, 224; 1944) has shown that certain strains of *B. subtilis* secrete pectinases which rapidly disintegrate pieces of raw potato when immersed in their solutions and which are concerned in the separation of flax fibres in retting.

From these investigations it would appear that some spore-formers of the *B. subtilis* group and *B. polymyxa* possess the necessary enzyme apparatus to attack and destroy the middle lamella of parenchymatous tissues under certain conditions, chief of which is the presence of water (not vapour), an adequate amount of which is necessary to start the enzyme system working.

The *B. subtilis* group has been recently investigated by Gibson (*J. Dairy Res.*, 13, 248; 1944), who has shown that this group of spore-forming bacteria can be considered as consisting of three main species each of which comprises a large number of closely related forms hitherto given distinct specific names. It seems possible, therefore, that failure to repeat some of the earlier work on the disintegration of plant tissues by some of these bacteria may be due to errors in identification. The possibility that other spore-formers may possess pathogenic powers as regards plants calls for further investigation and is much to be desired in view of the serious losses caused by bacterial rots.

# FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Saturday, October 28

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 3.30 p.m.—Mr. P. D. Saw: "New Types of Test Gear for Television Production".

### Sunday, October 29

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (joint meeting with the ASSOCIATION OF AUSTRIAN DOCTORS) (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 11.30 a.m.—Dr. F. Bergel: "Life Saving and Life Preserving Plant Products".

### Tuesday, October 31

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Mr. B. E. B. Fagg: "Some Archæological Notes from Northern Nigeria".

CHADWICK LECTURE (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Mr. Somerville Hastings: "The Management of Hospitals in Peace and War".*

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. S. Rodda: "Beam Tetrodes".

PHYSICAL SOCIETY (joint meeting with the BRITISH INSTITUTION OF RADIO ENGINEERS) (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "Physics and Radio".

### Wednesday, November 1

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. E. F. Armstrong, F.R.S.: "Chemistry in the Service of Man".

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. D. W. Kent-Jones: "Some Experiences of Microbiological Assays of Riboflavin, Nicotinic Acid and other Nutrient Factors"; Mr. W. N. Aldridge: "A New Method for the Estimation of Micro-quantities of Cyanide and Thiocyanate".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. E. B. Moullin: "Theory and Performance of Corner Reflectors for Aerials"; Mr. H. Page: "The Measured Performance of Horizontal-Dipole Transmitting Arrays".

### Thursday, November 2

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "Old and New Descriptions of the Astronomical Universe", (i) "Planets".

INSTITUTE OF FUEL (YORKSHIRE SECTION) (at the Royal Victoria Station Hotel, Sheffield), at 3 p.m.—Mr. H. C. Armstrong: "Improvements in the Use of Fuels in Everyday Practice".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. J. Bruce: "Electrostatic Precipitation of Dust from Boiler-Plant Flue Gases".

### Friday, November 3

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Dr. E. B. Bailey, F.R.S.: "Mountains that have Travelled over Volcanoes".

INSTITUTE OF PHYSICS (at the Institution of Electrical Engineers Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. E. F. Relf, F.R.S.: "Air and Fluid Motion".

INSTITUTION OF MECHANICAL ENGINEERS (in conjunction with the APPLIED MECHANICS GROUP) (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. A. J. Sutton Pippard: "Stresses by Analysis and Experiment".

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6 p.m.—Sir Stanley Goodall, K.C.B.: "Some Technical Developments in Naval Construction" (Andrew Laing Lecture).

### Saturday, November 4

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 10.30 a.m.—Discussion on Civil Aviation. General Critchley: "The Selection and Training of Personnel for Civil Aviation"; Major Thornton: "The Economics of Air Transport"; Mr. Roy Chadwick: "Civil Aircraft Design"; Mr. E. W. Hives: "Civil Aero-Engine Design"; Mr. W. P. Hildred: "Route Facilities (Radio, Aerodromes, Meteorology, etc.)".

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. L. Hawkes: "On Jet Coal in the Chalk of Kent".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

AGRICULTURAL TRAINING OFFICER to organize the scheme for the training in agricultural and horticultural occupations of men and women released from War service—The Executive Officer, Bucks. War Agricultural Executive Committee, County Offices, Aylesbury, Bucks. (October 31).

VISITING PROFESSOR OF GEOGRAPHY, VISITING PROFESSOR OF HISTORY, and VISITING PROFESSOR OF EDUCATION, in the Farouk 1st University, Alexandria—The First Secretary, Royal Egyptian Embassy, 75 South Audley Street, London, W.1 (October 31).

WATER SUPPLIES OFFICER, and an ASSISTANT LAND DRAINAGE OFFICER—The Chief Executive Officer, West Riding War Agricultural Executive Committee, Stray Hotel, Harrogate (November 1).

ELECTRICAL PLANT ENGINEER with first-class experience of both L.T. and H.T. equipment for an important Lancashire chemical engineering textile firm—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.932.XA) (November 2).

ENGINEERS OR PHYSICISTS (2) for Research and Development Department of Aeronautical Instrument Manufacturers (Hampshire area)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.647.XA) (November 2).

ASSISTANT (temporary) TO THE ADVISORY OFFICER IN MILK UTILIZATION—The Secretary, West of Scotland Agricultural College, Blythswood Square, Glasgow (November 3).

PSYCHOTHERAPISTS for work on a sessional basis with children and adults in the Psychiatric Out-Patient Clinic under the supervision of the Honorary Psychiatrist—The Secretary, Manchester Northern Hospital, 38 Barton Arcade, Manchester 3 (November 4).

HEAD OF THE ENGINEERING DEPARTMENT of Cardiff Technical College—The Director of Education, City Hall, Cardiff (November 6).

LECTURESHIP IN CIVIL ENGINEERING in the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (November 6).

CIVIL ENGINEER (Reference No. N.1163.A) and an ASSISTANT ENGINEER SURVEYOR (Reference No. E.1164.A) by the Department of Comptroller of Development and Welfare, West Indies—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (November 7).

CHEMICAL ENGINEER with good Science Degree and experience in design and development (preferably also of operation) of Heat Exchange Equipment and Chemical Plant generally, as Assistant in Technical Department of Gas and Chemical Plant Contractors—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2316.XA) (November 7).

COMBUSTION EXPERT who is accustomed to the application of scientific principles to large steam generators, by the London Power Company, Ltd. (a good Degree in Chemistry with Physics subsidiary, or vice versa, and research experience are desirable)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2240.XA) (November 7).

LECTURER (temporary, full-time) IN ELECTRICAL ENGINEERING SUBJECTS to Honours Degree and Higher National Certificate standards in the Cardiff Technical College—The Director of Education, City Hall, Cardiff (November 9).

GRADUATE TEACHER OF MATHEMATICS and/or SCIENCE in the Grimsby Technical College—The Director of Education, Education Offices, Grimsby (November 10).

GRADUATE ASSISTANT FOR GEOGRAPHY AND SCIENCE, in the School of Building, an ASSISTANT with ENGINEERING Degree or equivalent qualification in Structural Engineering, in the School of Building and Department of Engineering, and an INSTRUCTOR with experience in ELECTRICAL ENGINEERING, in the Department of Engineering, of the East Ham Technical College—The Secretary for Education, Education Office, Town Hall Annexe, Barking Road, East Ham, London, E.6 (November 11).

BACTERIOLOGIST on the staff of the Water Pollution Research Laboratory, Watford—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2248.A) (November 11).

CIVIL ENGINEER, and an ASSISTANT to the Civil Engineer, by the Government of Seychelles—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1167.A) (November 11).

LECTURER IN THE ELECTRICAL ENGINEERING DEPARTMENT, and a LECTURER IN MATHEMATICS—The Registrar, Technical College, Sunderland (November 13).

EDUCATIONAL PSYCHOLOGIST, and a PSYCHIATRIC SOCIAL WORKER—The Secretary for Education, County Education Offices, Northampton (November 13).

ASSISTANT LECTURER IN MATHEMATICS—The Registrar, The University, Manchester 13 (November 21).

PROFESSIONAL OFFICER (Grade I) in Ceramic and Refractory Research for the Government Metallurgical Laboratory, University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, W.C.1 (November 30).

RESEARCH WORKER (temporary) to assist in work on Fish which is being carried out in association with the Ministry of Agriculture and Fisheries—The Director, Freshwater Biological Association, Wray Castle, Ambleside, Westmorland (December 10).

DAVID JARDINE CHAIR OF ELECTRICAL ENGINEERING (with special reference to Electronics and the relations between Electrical Engineering and Physics)—The Registrar, The University, Liverpool (December 29).

LECTURER IN GEOLOGY (Grade IIb)—The Secretary, The University, Birmingham, 3 (December 31).

LECTURER IN MECHANICAL ENGINEERING—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

TEACHER OF MATHEMATICS in the Maidstone Technical Institute—The District Secretary, Kent Education Committee, 13 Tonbridge Road, Maidstone, Kent.

ADVISORY DAIRY BACTERIOLOGIST for the West Midland Province—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

KEEPER OF THE DEPARTMENT OF CERAMICS, TEXTILES, COSTUME and FURNITURE—The Director, City Museum and Art Gallery, Birmingham, 3.

ERECTOR SERVICE ENGINEER for the Sisal Control, Tanganyika Territory—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London W.C.2 (quoting Reference No. 1441).

# LAND USE AND SOCIAL ADJUSTMENT

THE scheme outlined in the White Paper on the Control of Land Use* issued by the Government in June last, together with a Bill facilitating the public acquisition, at 1939 prices, of damaged and decayed urban areas in Great Britain for planned redevelopment as single units, although following closely the recommendations of the Uthwatt Report on this aspect of the problem, had a poor reception. The merits of the Government scheme as a means of solving the particular problem of compensation and betterment have in fact been obscured by dissatisfaction with its attitude towards the wider question of land-ownership, and with its unwillingness to adopt a positive planning policy. The importance of the latter has been emphasized by events during the recess.

It is now accepted on all sides that planning control is necessary to secure the best use of the land in the public interest, that planning control is frustrated by the practical impossibility of balancing compensation and betterment under the present system of land ownership, and that therefore this system must be modified to the extent required to make effective planning control possible. Meanwhile, the question of the best use of land, as between the claims of housing and farming, of commerce and amenities, is a matter of the utmost urgency and importance. It is no longer a question of merely saving land : it is a matter of saving and using.

The news that Britain is to be increasingly searched for oil-fields, while welcome from the point of view of self-sufficiency in war, at least carries the risk of loss to our countryside which may outweigh any commercial advantage in the long run, and is clearly a matter to be determined by national considerations and planning. So too the controversies aroused by the proposed power-stations at Durham and Lincoln, the Highland water power scheme or even the City of London Plan and the Plymouth Plan, emphasize the imperative necessity of some real national planning of resources. Each plan proposes alterations, for the benefit of specific interests, to scenes which are generally regarded as part of the national heritage, and except in the Plymouth plan, where the proposals cannot be implemented effectively except as part of a national plan backed by national resources, there is little evidence that the wider national or regional interests have been considered.

The strong criticism advanced by Mr. Hugh Quigley of the North of Scotland Hydroelectric Board Scheme approved by the Secretary for Scotland in March has never been effectively answered and indicates the unsatisfactoriness of the general situation. Constructional Scheme No. 1, covering Lochs Sloy, Morar and Lochalsh, Mr. Quigley points out, forms no part of any plan for the Highlands. Provided with inadequate maps, it contains no reference to town and country planning schemes or to economic development of any kind. The Board, instead of

* The Control of Land Use. (Cmd. 6537.) Pp. 16. (London: H.M. Stationery Office, 1944.) 3*d*. net.

preparing its own schemes, appears to have accepted those prepared by consulting engineers or requested them to prepare such schemes, and, according to Mr. Quigley, there is no evidence that the final scheme was submitted to or approved by the Amenities or Fisheries Committee. Even now the main development scheme has not been published.

Mr. Quigley's criticism cannot but arouse profound misgivings as to the whole hydro-electric development scheme for Scotland, in any event while the Minister of Town and Country Planning possesses such inadequate powers. At present, instead of drawing up a broad master plan of how such areas of national concern as Durham, Lincoln, Plymouth and Oxford, the Highlands and London, the caravan camps and the housing estates, shall be handled for the good of all, he must depute the task piecemeal to representatives of those very interests at whose hands the community and the landscape have suffered much. Local authorities have not necessarily incentive or resources to weigh with strict impartiality the national against the local, the individual against the general issues.

In a small island such as Great Britain, the liberty of the community can only be achieved by some sacrifices of individualism, and the guardian of the community's landscape can only be a national ministry. Unless, however, Mr. W. S. Morrison's office is given much greater preventive and constructive authority than at present, local and individual interests may well continue to trespass in the names of freedom and progress upon that scenic heritage which is irreplaceable.

The situation is in fact even more serious than this might suggest. Despite the acknowledged need for regional planning and for redistribution and reform in local government, the Government has indicated that it has no present intention of embarking on local government reform. It may well be doubted, in fact, if the necessary inquiry could be brought to fruition in time for effect to be given to any recommended scheme of reorganization before action on immediate post-war reconstruction and development is necessary. Reorganization cannot be postponed indefinitely, as each successive measure of reconstruction in fields such as education and health and town and country planning shows, and Prof. and Mrs. J. R. Hicks' recent study, for the National Institute of Economic and Social Research, of the problem of valuation for rating indicates that the whole system may well break down for financial reasons.

None the less, the conception of such schemes as the plan advanced for Plymouth, with its striking evidence of the vision of at least some local authorities, should not lead us to forget the danger that such breadth of vision and national outlook may not be characteristic or universal. Furthermore, as the debates on the control of land use in the House of Lords and on the Town and Country Planning Bill in the House of Commons have shown, progressive local authorities may not be in a position to implement their own plans. It was made clear when the Plymouth Plan was first published that support on a national scale would be essential if some of its proposals were to take effect: it must be part and parcel of a national plan.

The position of Plymouth was described in the House of Lords by Viscount Astor, who pointed out that to carry out the Abercrombie–Watson plan meant that the future population of Plymouth would be limited to a maximum of 180,000 as compared with 220,000 before the War. It is impossible to expect a population thus reduced in size and with its rateable value further reduced as a result of war damage to bear the burden of such replanning; to preserve the values and population which are commonly described as 'overspill', Viscount Astor urged not merely financial help but also an amalgamation, so that people who earn their money in Plymouth but live outside continue to be citizens and that the values which move from Plymouth to the adjoining districts are preserved within the area as a whole. Lord Woolton, it is true, during the House of Lords debate, promised that some form of financial assistance would be made available for the acquisition by local authorities of approved open spaces where such acquisition would impose an undue financial burden on the authority, but this provision does not meet the situation created by 'overspill'.

Other cities and towns, such as Bristol, Cardiff, Dover, Great Yarmouth, Hull, Portsmouth and Sunderland, are in a similar plight, and their local authorities have appealed for legislative help by an amendment to the Town and Count y Planning Bill to enable them to replan these cities on modern principles. While the devastation of war has facilitated an immediate recasting of layouts, such cities have insufficient land to house their citizens if they plan according to modern ideas by including green belts and open spaces. To avoid serious loss and incurring heavy liabilities, they call for security now by an extension of their borough boundaries. They cannot afford the delay and uncertainty of another Bill for the general revision of local authority boundaries, which the Minister of Health hopes to introduce in a later session.

The amendment which was requested is of more than local interest. By it, if the Minister, on representations by a borough in which there has been specially heavy and widespread damage due to enemy action, was satisfied that the carrying out of an adequate planning scheme would be delayed or frustrated because the scheme would lead to a serious loss of population, he would be empowered to initiate an inquiry. The tribunal set up, after taking evidence from all interests likely to be affected, would have power to recommend an extension of the borough's area. With such an amendment the 'blitzed' cities would be able to go ahead and to act as planning laboratories for the whole country, providing an invaluable practical test of bold, up-to-date planning. To this amendment Lord Justice Scott has lent powerful support, pointing out that it averts the imminent danger of the country losing a splendid opportunity of putting into practice the Scott Report and the Barlow Report. The debate on this amendment showed clearly the difficulties involved in dealing with this particular

situation separately from the general question of local government boundaries and areas. Support for the amendment was not unanimous, although the urgency of the situation was generally admitted, and Mr. W. S. Morrison gave a convincing reply in indicating his inability to accept the amendment. The danger of prejudicing a settlement on broad and permanent lines of a wider question which is already under consideration by the Government is clearly great, and much of the force of the argument in favour of the amendment was withdrawn when it was announced by Mr. Morrison and by the Minister of Health that a White Paper on Local Government would be laid before Parliament before Christmas and that legislation would follow in the next session. The amendment was withdrawn; but the situation is a severe defeat for the Government's attempt at piecemeal measures and forces it back to first principles, by which alone the dilemma of the 'blitzed' cities can be resolved.

It cannot, of course, be maintained that the Bill and the White Paper are not very incomplete. The Bill deals with the particular problem of the acquisition of land in large blocks by local authorities for the purpose of planning the redevelopment of areas as units. The White Paper deals with the more general problem of seeing that the use made of land by its owners is not contrary to the interests of the community, that values created by the community are recovered for the community, and, conversely, that property acquired in good faith is not arbitrarily or discriminately confiscated by the actions of the State. In the atmosphere of prejudice created against the Bill, something less than justice was done both to it and to the White Paper, and their reception cannot but arouse misgivings as to whether the problems of reconstruction will be tackled in a scientific manner and with knowledge and realism. At least, with the qualification already noted, the Bill gives the local authorities the essential minimum of what they require and, freeing them from their paralysing uncertainty, enables them to proceed with their plans, even if in circumstances not quite so favourable as they had hoped.

Again, the White Paper, while lacking the simplicity of outright nationalization, differs from the Uthwatt proposals in several respects, but on the whole, the new proposals seem to be more clear cut and for that reason to be preferred. With the Bill, the White Paper represents the first major advance into a region that has been much discussed but little explored, and the Government's plan has the major merit of treating both urban and rural land on the same footing. Moreover, the decision to transfer responsibility for paying compensation and collecting betterment to a national land commission relieves local authorities of the need to permit as much development as they prohibit within their own areas, regardless of the dictates of good planning. The proposals do not foreshadow the appearance of that national plan which has also been promised, and the need of which has been emphasized by the inquiries at Lincoln and Durham as well as in the debates. In fact, the power given by the Bill to a few local authorities to start the positive planning of the use of land in their cities increases the urgency of the need for a national framework within which such local efforts can find their place.

Moreover, the matter becomes more urgent as the problem of employment is faced. The latest report of the National Trust* indicates the tendency. The most recent additions bring the area owned by the Trust up to 100,000 acres, with another 39,000 areas controlled, but the increase is less than in recent years and the rate of increase is likely to diminish in future. This is a probable consequence of comprehensive control by the State of the use of land, and the Trust will clearly require to give careful consideration in such circumstances before accepting large tracts of land, especially when situated in the neighbourhood of densely populated areas with potential demands for residential or industrial development. Again, if national parks are to be set up under the control of a statutory body of commissioners, the work of the Trust in those particular regions may diminish in importance.

What is clear from this report is that if the importance of the National Trust in saving land, such as beauty spots, for the nation is decreasing, its importance as a land user is increasing. With the large area now under its administration, the National Trust is concerned with estate management, farming and forestry on the grand scale. It has to see that preservation does not mean sterilizing our scenic heritage. Its policy, as in national parks, must be to combine the maintenance of the countryside at its best as a historic legacy, a place of recreation and a source of food, timber and minerals.

The combination of the highest efficiency in farming and forestry with the greatest measure of public access and with the fostering of bird, insect and plant life is no simple problem, and for the Trust is enhanced by the low fertility of much of its property. The report emphasizes the exceptionally experienced administration and control that are required. Yet another problem is that of the use to which many of the larger houses acquired by the Trust could be put, and difficulties in the way of adapting them either to institutional use or for recreation while preserving their character unimpaired.

This tendency, noted in the report of the National Trust, is even more marked when we come to consider the questions of industrial development and the re-location of industry. The replanning and rebuilding of our war-damaged towns and cities, like the planning of the countryside of Britain and the housing problem generally, as was well shown in the recent *Planning* broadsheet, "Location of Employment", is linked up with the question of employment. The houses must be built where the men and women who are to live in them will find their employment. Hence the importance of those proposals for the development of the north east of England advanced by the Northern Industrial Group, and of Lieut.-Colonel W. C. Devereux's proposals for the industrial reconstruction

* National Trust for Places of Historic Interest or Natural Beauty. Report of the Council for the Years 1943–1944. Pp. 62+8 plates. (London: National Trust.)

of South Wales, and more recently for the industrial development of West Cumberland.

What is significant here, however, is the consciousness in these plans in the *Planning* broadsheet and in the debates in the House of Commons on the Town and Country Planning Bill, that not merely is a better balance of industry and labour required, as is declared in the Government's White Paper on Employment Policy, but also the development of real communities.

This is the essential point brought out in a report of the Social and Industrial Commission of the Church Assembly, "The Church and the Planning of Britain"*. Emphasizing that physical planning alone is not sufficient and that industrial mobility has an inherent threat to domestic life and the stability of urban life, with consequent social disintegration for which no degree of physical planning, however wisely directed, can compensate, it directs attention to a problem which has frequently been overlooked. As the report notes, the liability of employees of banks and certain types of firms, especially those who have reached managerial positions, to be moved from one place to another, while frequently unavoidable, is adverse to the development of civic and religious responsibility and stability. Moreover, to the extent to which the incidence of such mobility is heaviest on those who have proved their capacity for responsibility and leadership, it tends to deprive the local community of those who would be its natural leaders.

If it is true that greater mobility must be part of the price we have to pay for social security and full employment, as Mrs. Gertrude Williams has suggested, it is important that every effort should be made to minimize any ill consequences. The Church Assembly report points to five ways in which the present housing situation and social and economic background fail to satisfy the basic psychological needs of men and women: the limitations imposed on family needs by its restriction of domestic space; the lack of connexion with man's vocational life; the encroachment upon leisure and the imposition of 'rush-hour' conditions involved in its remoteness from the scene of work; its false isolation and lack of facilities for a natural communal life; and the cramped character of the environment its creates, which denies opportunities for withdrawal.

From this point of view, the report concurs with Mr. Lewis Mumford's view that good planning in the post-war period will rest on the solid foundation of the family, and the region; it will emphasize the biological and social needs of the people, and treat industrial and financial needs as subordinate. Quoting the Barlow Commission's conclusion that the disadvantages in many, if not most, of the great industrial concentrations alike on the social, the strategic and the economic sides constitute serious handicaps, and even in some respects dangers, to the nation's life and development, the report urges that more important than the size or area of a town or conurbation is the expression of size as a function of the social relations to be served. Proper planning and adequate spacing must be demanded in old towns and in new units, and apart from amenities the report urges that those migrating from congested towns must be welcomed into real communities with social life, established or in contemplation, and with proper provision of churches and chapels, schools and playgrounds, halls and social meeting centres and theatres.

The insistence in this report that dispersal or decentralization must be based on the principle of the living community, with adequate facilities not only for housing but also for living, working, and recreation—a community in which local life is developed and generous provision made for the moral and spiritual needs of the population—is a welcome reminder that the problem of the right use of land is linked up with the central problem of democracy, namely, that of securing the framework within which its essential spirit can have the fullest possible play. It is the problem of morale which confronts us here, that of securing a better balance between industry and agriculture, between public control and private enterprise, and the fuller integration of industry with the needs of the community. Already the debates on the Town and Country Planning Bill have demonstrated the need for effective machinery for adjustment, and the complexities of modern life make the problem increasingly difficult and important. Whatever solution may be found to the immediate problems of the control of the use of land before reconstruction can proceed, there will be no final solution until we have solved this wider and deeper problem of developing the organization or mechanism by which a living community can adjust itself continuously to its changing conditions, retaining both firm control over its environment and at the same time the freedom which the human spirit requires for its intellectual, moral and spiritual development. The proper way of planning things, as the Church Assembly report notes and experience has shown, is to secure the kind of structure which ensures that individuals and small groups in co-operation shall learn to control the material and the administrative adjustments of their own immediate surroundings, and so gain larger insights into, and control over, the wider world of affairs. If we are to save freedom we must proceed, as the late Archbishop of Canterbury has reminded us, from democracy of the individual to democracy of the person, and recollect that personality achieves itself in the lesser groupings within the State—in the family, the school, the guild, the trade union, the village, the city, the county. No physical planning will serve the needs of the post-war world which does not provide for the fostering of these and like loyalties, which have sprung up in civil defence and other activities under the stress and demands of war.

Such objects of loyalty can and do contribute to the wealth of tradition and inheritance of the State and thereby to its stability. Already the storm over the compensation clauses in the debate on the Town and Country Planning Bill has shown that, unless such loyalties are subordinated to, or rather integrated into, a higher loyalty, there can be no hope of solutions to problems so essential in the national interest. As

* The Church and the Planning of Britain. Report of the Social and Industrial Commission of the Church Assembly, 1944. (C.A. 753.) Pp. 32. (London: Church Assembly.) 2s.

the Prime Minister rightly said, for all its shortcomings the Bill is needed, for without it planning and reconstruction cannot proceed. The appeal to national unity and to a spirit of reasonable compromise will, it is to be hoped, be heeded. That such an appeal should have been necessary at this late hour is an unmistakable warning of the urgency of much greater attention to this question of public morale, and the fuller integration of group interests and loyalties with the larger and wider interests of the community. Important as may be the service which science can render in different ways to the planning of the use of the land and other material resources, it might make an even more significant contribution to the vast field of post-war reconstruction by an adequate attack on the problems encountered in the field of public relations—what Lord Stamp described as the science of social adjustment.

## THE STORY OF ANATOMICAL EXPLORATION

**A History of Comparative Anatomy**

From Aristotle to the Eighteenth Century. By Prof. F. J. Cole. Pp. viii+524. (London: Macmillan and Co., Ltd., 1944.) 30*s*. net.

INTEREST in the structure of animals must have occupied the mind of man from remote antiquity, ever since they were the object of the chase and required to be prepared for food. Even palæolithic man indicated the surface anatomy of vital organs in his mural paintings of animals, and occasionally exercised his artistic propensities in making exquisite carvings of the flayed heads of horses, depicting the muscles with remarkable precision. From time immemorial, also, primitive communities have shown the liveliest interest in the individual variations of the visceral anatomy of domestic animals, using these variations as omens on which to base decisions of policy. But the study of comparative anatomy, which is essentially the search for common denominators in organic structure, is a scientific method, and could only be the product of philosophic inquiry into the meaning of life and living things.

It is with the history of this approach to biological problems that Prof. Cole deals in his brilliant treatise on the development of anatomical practice and thought from the time of Aristotle up to the eighteenth century. It is true to say that many biologists have been impatiently waiting for this book. Prof. Cole's erudition and scholarship as a historian of biological science are well known, and there is no doubt that in his particular field of study he stands pre-eminent to-day. In his preface the author informs the reader that he had originally intended to write an exhaustive history of zoological discovery, based on protracted and laborious searches carried on during many years. Considerations of brevity imposed by present-day circumstances, however, compelled him to put aside for the present this project, and he has contented himself with a more limited objective. But if the objective was necessarily limited, the result is highly impressive.

To the comparative anatomist whose acquaintance with the historical development of his subject is not so intimate as he might wish, a glance through Cole's book will cause surprise at the wide field covered by the old comparative anatomists (particularly of the sixteenth and seventeenth centuries), at their meticulously detailed descriptions, at the artistry and accuracy of their illustrations, and at their technical skill. A closer reading leads one to ponder on the motives and incentives which led to the development of this science, and suggests a continuous repercussion of two main driving interests. One of these is the ever-present urge in the human mind to reduce order out of chaos, to classify, and to search for a common plan underlying a profusion of variety. So arose the systematists who, beginning with Aristotle, gradually worked up to the impelling conception of the *Echelle des êtres*, which dominated the minds of zoologists in the immediately pre-Darwinian era. Belon, Rondelet, Aldrovandus, Coiter, Gesner and others represented this field in the sixteenth century. Belon's work is noted for his study of homologies in the human and avian skeletons, and he may perhaps be regarded as the initiator of the science of pure morphology. Coiter's magnificent publications on comparative osteology arouse admiration largely because of the superb illustrations executed by himself. His figure of the articulated skeleton of a capuchin monkey, for accuracy of delineation and effectiveness of technique, would be regarded as excellent in any anatomical monograph of to-day. Incidentally, it might be interesting to investigate the correlation between anatomical achievement and artistic ability, for both require an aptitude for visualization of an unusual kind. It seems not improbable that some of the anatomical books which appear in modern times really owe their origin to the pleasure which the authors obviously experience in illustrating them.

Despite the care and thoroughness with which medieval systematists conducted their studies, it is remarkable that they were often unable to break away from purely popular conceptions of classification. For example, the porpoise seems to have occupied the puzzled attention of several comparative anatomists—Belon in 1551, Ray in 1671 and Tyson in 1680. Yet, in spite of the evidence of their eyes, they continued to classify it with the fishes. But it is evident that this conservative view was accepted with some reluctance. Tyson remarks that when we view the porpoise externally there is nothing more like a fish, but when we look within there is nothing less like one. He even says he would *like* to think it is not a fish, but this is as far as he is prepared to go in the face of popular assumption. Although Tyson's anatomical studies covered a wide field of vertebrates and invertebrates (among other things he gives the first anatomical description of a marsupial), he is perhaps best known for his study of the chimpanzee, a noteworthy contribution to the study of systematics, for it brought man himself into much more direct relation with lower mammals. The chimpanzee, he concludes, is "no *Man*, nor yet the *Common Ape*; but a sort of *Animal* between both".

Comparative anatomical exploration during the latter half of the seventeenth and the first half of the eighteenth centuries was very prolific, but was pursued with little attempt at the formulation of general principles of morphology; so that, as Cole points out, Vicq D'Azyr in 1786 was concerned to direct attention to the masses of undigested and incongruous facts which had been assembled and to complain that they tended to produce a feeling of fatigue and weariness in the reader. Yet it was this

field of study which led to the development of the transcendental philosophy of anatomy in the early part of the nineteenth century, a philosophy which, although sterile in itself, was almost a necessary precursor of the evolutionary conceptions which rapidly followed. At the same time, it is a remarkable fact that, as E. S. Russell points out in his book "Form and Function", when the evolutionary conception was at last raised to the level of a scientific hypothesis, it was from pure morphologists such as Cuvier and von Baer that the most violent opposition arose.

We have noted that one of the incentives which initiated the study of comparative anatomy was the innate tendency of the human mind to systematize and classify. The other powerful incentive arose from the development of medical science. It is easy to understand that, in the period when the difficulties in the way of dissecting human corpses were immense, zootomy became a common practice as an indirect method of approach to the study of human anatomy. Indeed, as is well known, some of the early descriptions of human anatomists were vitiated by the fact that conditions peculiar to lower animals were sometimes reported as normal for man. Even Galen and Vesalius bear some responsibility for such errors. But, apart altogether from considerations of practical necessity, many human anatomists of the sixteenth and seventeenth centuries deliberately studied animal structure in the belief that their simpler organization might provide an opportunity for determining functions which are obscured by too great a complexity in man. This, of course, is one of the essential aims of comparative anatomy and was the view of Casserius in 1601 when he expressly claimed that the fabric of man could be explained by reference to lower animals, and of Samuel Collins, physician to Charles II, who wrote in 1685, "I humbly conceive the great use of comparative anatomy is to illustrate the structure, actions and uses of the human body".

The idea was grandly conceived, but the records of comparative anatomy up to the present time have disclosed the limitations of such a method. Even Malpighi was constrained to confess in the introduction to his "Anatome plantarum" (in 1675) that he had been disappointed in its results. But the study of comparative anatomy with reference to human structure and functions was fully vindicated by the realization that lower animals could be made the subject of experimental investigation, and for this purpose the establishment of homologies and analogies in the structure of different species became a most essential preliminary. The significance of comparative anatomy for the experimentalist was evidently realized by a number of early anatomists, starting with Galen. But it was Harvey who first developed this method of approach in the study of human functions, though, as Cole emphasizes, to him the lower animals were also worth studying for their own sake and for the light they throw on the fundamental truths of biological science. It is possible that even to-day the limitations of pure comparative anatomy as a method of elucidating function are not always fully recognized. It is a method of the utmost value as a preliminary survey for experimental investigation, and it can often offer important clues and hints to the physiologist, but it may be doubted whether comparative anatomy *by itself* has ever been able to supply the final proof of the function of any structure the significance of which is in any way obscure.

In the concluding part of his book Prof. Cole discusses the value of a knowledge of the history of scientific learning to the modern man of science and rightly urges that more attention should be given to it in the educational curriculum. Among other things, it helps to develop that sense of humility which is surely a desirable attribute for the research worker who aims at high achievement. But we would demur from Prof. Cole's suggestion that "future generations will view with amusement the involved jargon and mechanical elaboration which condemn the chromosome theory of heredity and remind us of the evanescent frenzy of the nineteenth-century transcendentalists". After all, the modern geneticist can claim that his conclusions are based, not on superficial analogies and philosophical abstractions, but on a solid abundance of carefully controlled experimental work.

Prof. Cole's book is without doubt one of the great works on the history of biological science. It is the product of mature thought and many years of bibliographical research, and the fact that the author himself is a professional biologist gives it additional value. In spite of war-time restrictions on the quality of paper available for a production such as this, it is extensively adorned with excellently reproduced illustrations. It is to be hoped that Prof. Cole's original intention to write a much more comprehensive work on zoological discovery will find its realization before long.

W. E. Le G. Clark.

# PROBING THE METABOLIC SECRETS OF THE TISSUES

## Creatine and Creatinine Metabolism

By Prof. Howard H. Beard. Pp. x+376. (London: Chapman and Hall, Ltd., 1943.) 24*s*. net.

SINCE Prof. A. Hunter published his monograph on "Creatine and Creatinine" in 1926, much experimental evidence has accumulated. At intervals since then there have been reviews but probably none so full as the present monograph by Prof. Beard. His contribution represents a fresh approach to the problems of creatine and creatinine metabolism.

Creatine is the chief nitrogenous constituent of muscle tissue, and the author submits reactions to illustrate the synthesis of creatine and creatinine *in vivo* and *in vitro*. Despite the fact that glycocyamine has long been recognized to be methylated to creatine in the animal body, its role as a creatine precursor has not apparently been accepted until recently.

It is held that the mechanism for creatine synthesis from urea and glycine resides in the muscles, while that of arginine and glycine resides in the kidney, and that methylation takes place in the liver. The muscles, liver and kidneys are apparently the tissues chiefly concerned with the formation of creatine and creatinine from most of the amino-acids of the diet. It is also certain that creatine can arise from creatinine *in situ* in the body and also in *in vitro* studies.

The author considers that from data secured in 1925 he was able to obtain probably the first definite evidence against the distinction between exogenous and endogenous metabolism. The recent brilliant work of Schoenheimer *et al.* in this field has shown that the newly formed creatine (and creatinine) molecules acquire their parts from the food as well

as from tissue components, for example, the amino-acids, arginine and glycine. This is taken as further evidence against the concept of two independent (exogenous and endogenous) types of catabolism. H. H. Mitchell, on the other hand, appears to hold that tissue creatine is very constantly undergoing dehydration to creatinine (which is eliminated by the body as a useless metabolite); that it is being constantly formed, and that the rate of its synthesis cannot be readily accelerated by an over-abundance of its precursors in the tissues, nor by the administration of amino-acids. The author, however, considers that creatine and creatinine represent uniform rather than constant metabolites, and their formation and excretion are governed by the rate of protein metabolism, and that Mitchell has not really offered evidence to refute Schoenheimer's views.

There is at present a considerable difference of opinion as to whether the feeding of gelatin (with its high content of glycine), or glycine itself, will increase the energy output in man. In Prof. Beard's experience only 75 per cent of a given number of individuals will show increases in energy output, with the other 25 per cent exhibiting nothing after glycine or glycine-urea ingestion. This he considers to be a normal physiological variation between individuals and should be recognized as such. It is held by the author that glycine will not form creatine unless a normal or high protein diet is fed at the same time, as otherwise the glycine or the amino-acids hydrolysed from gelatin will go first to meet this demand. Although the author believes in the beneficial action of glycine the case for glycine is, on the balance of evidence, 'not proven'.

Much of what is described here is still highly controversial and is certain to stimulate much discussion. If a fault may be found it relates to the author's enthusiasm for the role of glycine in the treatment of varied clinical conditions. It is here that he will probably encounter most criticism; but although his account appears to have this bias it will most certainly have been of value if it stimulates further work.

D. P. CUTHBERTSON.

## PLASTICS MADE EASY

**Plastic Horizons**

By B. H. Weil and Victor J. Anhorn. (Science for War and Peace Series.) Pp. ix+169. (Lancaster, Pa.: Jaques Cattell Press, 1944.) 2.50 dollars.

THIS little book is worth careful examination, for it may represent the kind of thing with which the public is fed or doped in the days to come. In the 'blurb' on the dust cover it claims to take up where the newspaper articles and institutional advertising leave off. It is a back-to-earth job in which curiosity and interest in plastics will be supplanted by actual working knowledge. To use the author's favourite expression it may, and then again it may not.

The book starts well from the conception that we can scarcely help noticing the world around us: countless changes begin to intrigue our fancy and stimulate our imagination. This is largely true of America, thanks to a Press which is more and more prepared to direct attention to the progress of science and to display attractive advertisements which make names and processes known to a public which is ready to accept anything new. It is far from true of Great Britain, where the masses are conservative. Proof of this is afforded by the reception given to the 'Portal House', which represents quite the finest step forward in domestic engineering of this century. The British Press has not yet learned to talk about science, its occasional efforts are too often characterized by exaggeration and inaccuracy, our advertising is poor. Scientific workers as a class do not want publicity, least of all that which is associated with a particular name, often the wrong one.

Assuming we have an interest, such as our forefathers did, in the things we use, what can we learn about plastics? The word is now an accepted one though it involves a contradiction, and we use it as descriptive of a large number of substances which the chemist makes of the most diverse properties—billiard balls, 'Nylon' stockings, telephones, glues and lacquers. I think we should encourage the definition that the chemist makes them from a few simple substances which he can procure quite inexpensively in quantities of thousands of tons, for it leads to the next question, How does he make so many different things from these few starting materials? The authors plunge us into structural chemistry and are not afraid to cover several pages with structural formulæ, which inspires a wholesome respect for it and the molecular engineers who follow its precepts. The phrase is a good one, for those who engage in synthetic chemistry are 'molecular engineers' building up from small molecules, with only two atoms of carbon, and thus comparable with bricks, a mighty structure composed of thousands of molecules. These molecular chains vary; when they are long and contain little interlinkage they can be worked and re-worked and are termed thermoplastic. But if there is much cross-linkage between the chains the first heating sets up a rigid molecular structure and the product is thermo-setting.

The authors get us thus far in fifteen pages, and it will be admitted that they have done a good job in getting the idea of molecular structure across. The book goes on in this fashion, telling us about moulding, about particular resins, how they are made and from what materials—our interest is continually stimulated. But people are most interested in uses, for war to-day and for peace purposes to-morrow, so we are told something about these. This section is rather superficial and too much a catalogue without indication of the why and wherefore of its use: the chapter is below the standard of the early part of the book. The authors have more scope when they come to synthetic fibres and synthetic rubber, two things about which the public really want to know; the chapter contains a lot of information and an indication of the competition to be faced.

The final subject, plastics and the future, is one which gives scope for the enthusiast; but the authors, while stimulating, are commendably restrained. Plastics will supplement rather than supplant the traditional structural materials, applications will multiply, prices will grow less, the versatility of the materials will find new uses for them, but we are not on the eve of a plastics age nor will their use solve all the problems of man.

I have written enough to show that I find this a readable book, written on a high level though essentially popular, and one which would help in the understanding of what the chemist is doing and can do if it could only reach a large section of the public. I think it fulfils the authors' aspirations.

E. F. ARMSTRONG.

# ROBERT WIGHT (1796–1872), DR. FREKE AND THE "ORIGIN OF SPECIES"

By T. E. T. BOND
Tea Research Institute of Ceylon

AN interesting sidelight on the Darwinian controversies of the early 1860's is afforded by some fragments of contemporary correspondence which have recently come to my notice and which are worth placing on record as much for their subject as for their intrinsic merit of style. The documents accompanied some volumes of Robert Wight's Indian botanical works—the "Illustrations of Indian Botany" and autographed copies of the "Spicilegium Neilgherrense" and vol. 6 of the "Icones Plantarum . . ."—generously loaned to the library of this Institute by his great-grandson, Mr. H. C. Cosens, who is a Ceylon tea planter. They consist of four draft letters in Wight's handwriting addressed to Dr. Freke, of Dublin, on the subject of two pamphlets by the latter author which are also preserved with the letters. Freke is largely concerned with establishing the priority of his own views over others which he attributes to Darwin; Wight, in his letters, has some trenchant observations of his own to make as to the relative merits of the conclusions reached by these two authors. I have no means at present of finding out whether the final version of the letter was ever sent or, if sent, whether it is still in existence; nor have I the opportunity of following up many of the points of historical and biographical interest which are raised by this material. In this article I shall not attempt to do more than briefly introduce the two characters concerned and thereafter, so far as possible, allow the papers to speak for themselves.

Robert Wight left India in 1853, so that all his botanical works while in that country might be expected to have a 'pre-Darwinian' flavour. As anyone who is in the least acquainted with them will know, they are indelibly stamped with his own forceful and vigorous personality in addition. The blending of the age and the man is seen nowhere to better advantage than in his preface to the "Spicilegium Neilgherrense", written, presumably, in 1846. A follower, for practical purposes, of the de Candollean modifications of Jussieu's system, he here enlarges on the desirability of attaining to a still closer approximation of "the true Natural System of Botanical classification, now so ardently sought for by all philosophical Botanists". He is indeed well aware of the difficulties in the way, not the least of which is that, as he says, ". . . even the most learned and philosophical among them, seem not to know quite clearly what they are in search of and of course can scarcely be expected to inform others what they do not well understand themselves".

Having disposed of the argument that the natural system "is neither more nor less than a human contrivance", and demonstrated that there can only be one such, namely, that which repeats the design of the Creator, he proceeds to show that the "*Circular* method" affords the best clue to its discovery. The system that is favoured presupposes a ternary, or rather quinary, subdivision of the animal and vegetable kingdoms by analogy with the three primary circles of affinity, namely, "Animals being the typical circle, Vegetables the sub-Typical and Inanimate matter the Aberrant; which last is made up of three minor ones the endless modifications of Earth, Water and Air; each equally perfect, thus making together a series of five". All is well so far as the first stage in the subdivision whereby, for example, the exogens (or dicotyledons) are revealed as analogous with the vertebrates. Afterwards, however, "the Zoological system . . . seems to have gone far ahead of the Botanical" and even in the latest systems of Lindley and of Endlicher, which are briefly noted, no satisfactory quinary subdivision is attained for the primary exogenous and endogenous groups. To make good this deficiency, Wight then sketches out a provisional quinary classification of his own, using many of the Lindley and Endlicher class names. His groups, he says, "have a circular appearance and give promise that . . . their thorough investigation may put us on the right path and speedily enable us to reach the long and anxiously sought for goal". For Wight, "to discover these [circles], if they actually exist in Nature, appears in the present state of enquiry to be the first and grand desideratum towards the discovery of the true Natural System of plants".

While Wight was speculating on the logical advantages of the one true natural system of classification as revealing the orderly plan of the Creator, Freke was developing a system whereby the actual process of creation could have been effected. His ideas in the main appear to have been derived from Bichat (1771–1802), who postulated "that the life of the body is the outcome of the combined lives of the constituent tissues" (Sir William Dampier, "A History of Science", 3rd edn., p. 274). For these tissues, Freke infers an ultimate common origin in a primordial form, the "embryo of organic creation". He thus claims to be the original propounder of the doctrine of descent and stoutly maintains that it is he, and not Darwin, to whom credit for this doctrine should be given. In a short paragraph devoted to Freke in the historical introduction to the revised edition of the "Origin of Species", Darwin refers (p. 19) to "the difficult attempt to give any idea of his views"; indeed, not without reason, as will be demonstrated in the ensuing paragraphs.

Freke's earlier pamphlet is evidently a reprint of the circular mentioned by Darwin (*loc. cit.*), which was published originally in October 1860. It consists largely of quotations from the author's articles in the *Dublin Medical Press* of the years 1851–52, and in its present edition takes the form of a prospectus for his book "On the Origin of Species by Means of Organic Affinity", newly published in 1861. The title is an obvious counter to Darwin's work to which, he says, surely with studied under-emphasis, "My attention has, within the last few days, been directed by the merest accident . . .—a work, which as I have been given to understand, is at the present moment attracting a large share of public attention". His position is soon defined; following the review (presumably Bishop Wilberforce's) in the *Quarterly*, and with entire neglect of the principle of natural selection and the arguments upon which it is based, he quotes Darwin's statement that "Analogy would lead to the belief that all animals and plants have descended from some one prototype" as the sole point at issue. He "feel[s] it to be due, as well to myself as to science, to acquaint the physiological public that although that theory has now been reached through a different channel, it has not *now* been announced for the first time. *Nine years* before the appearance of Mr. Darwin's publication, I, as the

result exclusively of *inductive* inquiry, submitted this *identical hypothesis* to the judgment of physiologists —a conclusion which Mr. Darwin has since attained to by *analogy*".

The original announcement of the theory is supported by the first of the quotations from the *Dublin Medical Press* of November 1851. In this, Freke presents as an important subject of physiological inquiry the distinction between the organic world "*at the period of its creation*" and at "its present *advanced stage of development*". The second paragraph of the quotation is worth reproducing in full, with Freke's italics and parentheses:

"The line of investigation which (as it appears to me) should be pursued in such inquiry is the following—namely, I should endeavour to ascertain,—first, what is the constitution of organic creation as it *now* exists; or in other words, what is the constitution of the *present generation* of organised being? and secondly, how or *in what manner* has the present generation been *generated* or formed by the preceding generation? A knowledge of these two facts would (as I conceive) furnish us with data from which to collect a certain amount of information as regards the *necessary* constitution of the *origin* or (if I may venture to term it) of the *embryo of all generations*. For if the manner in which organised beings universally have been generated can be *accurately* traced back for *one* generation, there is nothing to prevent its being, with equal accuracy, traced back for *many*; and *the possibility* is that it may, with a certain degree of accuracy, be traced back *for all* generations; that is, in other words, till we have eventually arrived, in imagination, at (if I may so term it) the *embryo* of ALL organic creation".

Pursuing this inductive inquiry on the assumption that all individual living beings "*have been formed by the union of a number of minute organisms*", or "organizing atoms", he reaches the conclusion (at first sight almost a foreshadowing of the discovery of the linear arrangement of genes in the chromosome) that the "embryo of organic creation" consisted of "a chain composed of perhaps but a few individual microscopic granules".

Later in the same article, the nature of this chain of organizing atoms is further defined. Each atom is to be regarded as a "*distinct species of organizing matter*", with the common function, however, of indefinite self-regeneration through the process of imparting ever higher degrees of organization to the "organized residual products" of the atom beneath it in the chain, the lowest atom of all having as its substratum of activity "the unorganized or mineral world". The various "organizing atoms", by uniting in various ways, were supposed to constitute the "*first or earliest embryos*" of different plant and animal species, their "organized residual products" similarly combining to form "the various compound residual products required by Nature to enable those embryos to discharge their physiological function". "This, I say, appears to me to have been the origin of species by means of what I have ventured to term *organic affinity*". Freke is no believer in evolution in the Darwinian sense: he is concerned merely with the formation of "*the first generation* of living beings", not with any possibility of their subsequent modification by descent. Indeed, he is at pains to emphasize, beneath the title of his book, that "Nothing is advanced in this publication that is not perfectly in harmony with the Mosaic record of Creation".

So far, it is not difficult for the modern reader to find in Freke's "organizing atoms" and their products an analogy with his own concepts of genes, organization centres, etc.; but the author soon makes it clear that he has in mind categories of much more limited anatomical significance only. This is developed in the postscript to the above quotations and especially in the second of the two pamphlets, which is dated October 1862.

The heading of the second pamphlet (considerably shortened) runs:

"TABULAR VIEW of the relation . . . between the Three Kingdoms of Nature with regard to Organization; including that subsisting between Organiz*ing* Agents and Organiz*ed* Residual Products . . ., shewing at the same time the Circle of the same elementary components . . .; and pointing to the nature of the *dependency* of LIFE upon DEATH in both the Vegetable and the Animal Kingdom".

The pamphlet chiefly adds the names of the "organizing atoms"—*lignat, musculat, celebrat*, etc., with, rather surprisingly, *georgat* as the first of the vegetable series—"the simple germ (or atom) which organizes earth". Finally, the dependence of life upon death is illustrated by considering the difference between the plant and animal worlds, the "*organic life*" of plants involving merely the death (and simultaneous regeneration) of *organizing agents*, the higher form of "animal life" involving in addition a second species of death, namely the death of the *organized residual products*. As evidence of this, the indefinite increase in size of the plant body is contrasted with the fixed size of the animal. The views expressed in this second pamphlet are traced in part to an essay published in 1848 ("Freke on Organization"), in part to the article, already referred to, in the *Dublin Medical Press* of 1852.

Reading Freke's pamphlets, one cannot help but admire his apparent ingenuity and fertility of imagination, even while exasperated and amused in turn by the redundancy of his style. It is not for me to assess the originality of his ideas; but at least it is surprising to find him omitted from the "Dictionary of National Biography". Here, only "John Freke (1688–1756), surgeon" and "William Freke (1662–1744), mystical writer", find a place; and either, one feels, would have been an appropriate forbear.

That Robert Wight, no less than Darwin, found it difficult to deal with Freke's views is apparent from his manuscripts, which can now be described. The letters were written in Wight's retirement, presumably from Grazely Lodge, Berkshire, and from the internal evidence they can be dated to within the first fortnight or so of December 1862. Three out of the four can fairly easily be arranged in order: the first (about three hundred words, in pencil on the back of a seedsman's circular) is apparently a rough draft for the second (about 550 words) which, in turn, was expanded into the third (about a thousand words), written a week later. Of these, I propose to give extracts, making, so far as possible, a continuous narrative, the references in brackets (1–3) indicating the source of the material as described above. The fourth, which is unfortunately a fragment only (about three hundred words, on a half sheet of paper, apparently with a preceding portion torn away) is less easy to place; being in addition rather lighter and more personal in style as compared with the others, it may be quoted, almost in its entirety, as a fitting tailpiece to the series.

In the opening paragraph of (2) and (3) there is a reference to some earlier criticisms made by Wight, apparently well received. These perhaps related to the pamphlet(s), Wight being presented afterwards with copies of the author's books, as mentioned in the letter:

"My Dear Sir,

"I am ashamed to have to begin my letter with the confession that at least 10 days have elapsed since I had the pleasure of receiving your letter of the 22nd and the books which arrived the day after. I accept them with many [thanks] and hope we shall some future day have the pleasure of becoming better acquainted. I was exceedingly pleased to learn that my criticisms were so well received for, to tell you the honest truth, I was very fearful, when I read over for the last time what I had written, that on some points I had been much too severe and thought of either suppressing my letter altogether rather than hurt your feelings further after the strain to which they had already been put, or write the whole over. The latter alternative was out of the question so I determined to send it on, hoping for the best. Since happily you think the criticism was not really unjust and was written in a really friendly spirit let us bury the objectionable parts in the saying that ''tis all well that ends well'.

"Since the receipt of your volumes I have been reflecting a good deal on your and Mr. Darwin's views on the origin of species and right or wrong have arrived at a conclusion somewhat different from both. You say you have arrived at a conclusion 'as the result exclusively of *inductive* enquiry' which Mr. Darwin has since attained to by *Analogy*. In this statement I think you have fallen into an error. To my mind, induction is the process employed in both cases, with this difference, that the inductive process begins at opposite ends. He reasons backwards from the perfect plant and animal to the primordial germ, whereas you reason from the assumed germ onwards to the perfect animal. He says 'I cannot doubt that the theory of descent with modification embraces all the members of the same class. I believe that animals have descended from at most four or five progenitors and plants from an equal or lesser number'. That is the theory arrived at by induction. He then adds that analogy would lead one one step further, namely to the belief that all animals and plants have descended from one prototype: and adds that analogy may be a 'deceitful guide'* ; and then winds up by saying that he would infer from analogy that probably all organic beings that ever lived have descended from one primordial form *into which LIFE was breathed by the Creator*. His theory, then, rests on a persevering close induction carried on through 480 pages; the finale only is an Analogical inference. And that inference I think questionable.

"You, on the other hand, assume that the Creator imparted life to a germ which then went on multiplying itself and your induction, resting on that assumption, goes to show that such must be the case. The induction therefore, every step of which may be unquestionable, rests on a postulate which you can't prove. Darwin's, on the other hand, rests in the first instance on unquestionable facts, the known tendency of both plants and animals to form variations" (3).

Although the logic of Darwin's argument is thus favourably contrasted with Freke's, his conclusions are not thereby rendered acceptable. This is well brought out by reference to an earlier version, namely:

"Darwin being a laborious painstaking man and a deep very cautious thinker started on his course of investigation, which for twenty years he has never ceased to follow up, from certain undeniable data of every day occurrence among both Animals and Vegetables, their liability namely under certain circumstances to variation. Then, calling in the aid and experience of the breeder and gardener and allowing unlimited time he has as he supposes traced back organization to a point or at most a few points or monads or primordial germs or any other name you may prefer but still admits that these germ or germs must in the first instance have derived its vitality from a higher [? source]. Working on that idea for 20 or more years he has ransacked every source of information which he can directly or indirectly bring to bear on the subject and has made a very interesting book, heavy at times to read from his peculiar style, but to my mind lost labour for it leads to nothing, does not advance our knowledge of the origin of vitality and only claims for it powers which all our experience goes to disprove. . . ." (1).

* A quotation conveniently omitted by Freke.

A big stumbling-block is the apparent fixity of living species and the difficulty of envisaging modifications of the size demanded by the evolution theory. As Darwin puts it . . . "we are always slow in admitting great changes of which we do not see the steps".

"A grain of pollen the 100,000th part of an inch in diameter is placed in contact with the pistil of its own species and a great tree results; but apply the pollen of an Oak to the Alder or Pine or any other genus but its own and it fails to impregnate the ovum. This law holds throughout the whole vegetable kingdom . . .

"From this I infer that the Deity in creating organic germs, supposing that was his mode of proceeding, imparted to each its specific character, which, with some modification, it still retains; by which it is permitted to vary within certain limits. The Gardener produces floral varieties in any number but he can't change an apple into a pear nor a cherry into a plumb [*sic*]. The pigeon breeder can by selection and careful breeding obtain many varieties among the species of that genus but can't change a pigeon into a hawk, and won't the same law hold good through the whole of the organic kingdom? Specific variations are everywhere observable, but not transitions from one natural order or genus to another (2).

"It is difficult if not quite impossible with almost any stretch of the imagination, assisted even by myriads of years, to fancy such an unit as a Byssus becoming a lofty Palm, or a monocotyledonous grass an umbrageous oak" (3).

But the biggest difficulty of all, in accepting either theory, is the philosophical one: the element of chance is felt to play too great a part. Wight, as much as Freke, ignores completely the force of natural selection.

"Since reading Darwin's volume, I have thought much of his theory as summed up in the concluding page and with every wish to view it with a favourable eye I cannot bring [my] mind to accept it as a correct exposition of the Creator's plan in covering the earth [with] its organic inhabitants, vegetable and animal. We can in imagination conceive the deity imparting to certain atomic elements the force called life, enabling them to impart the same force to others of the same kind just as a spark falling among suitable materials will raise a great fire, but I cannot accept the idea that out of such materials—shapeless vitalized atoms—the wonderfully complex organisations each and all possessing the most perfect adaptation to its wants could ever have been derived without the aid and guidance [of] omnipotent power and inscrutable wisdom. From the first promulgation of the idea as deduced from Analogy my question has always been, what does Philosophy gain by its adoption? The aid of the Deity is required to set life in motion, why then limit his power to the mere giving of life, leaving it to circumstances to determine its forming a shapeless puffball or a man? (2).

". . . having required the aid of Omnipotence to organize our first atom it behoves us to return to the same source and solicit inscrutable wisdom to superadd those laws of combination and arrangement which we find prevailing throughout organic existence. . . . I go a step further and add that since the aid of the Deity is needed in the first instance to impart life and organisation, that organic philosophy gains nothing whatever—it may lose—by adopting the doctrine [of] the creation of a solitary primordial form—germ or atom, call it what you will—and leaving all the rest to secondary causes" (3).

To Wight then, 'organic philosophy' carried the day and the evolutionists were found wanting. The order and logic of the natural system with its quinary circles of affinity were perhaps more to his liking than

the ruthlessness of natural selection and the improbabilities of the "embryo of ALL organic creation". But at least the issue was not decided without much thought. Of all the four versions of the final verdict which have survived in these manuscripts, none is more characteristic than that which follows, in conclusion :

"... But I now find that were I to attempt extending my notes on the subject they would form quite an essay . . ., while my imperfect acquaintance with the science of the present day would to some extent disqualify them for publication in the state they flowed from my pen. As mere suggestions to help a master mind they might perhaps be useful, but scarcely otherwise. But be that as it may, I am not by any means satisfied in my own mind that either of you have attained the desired goal though you attempt to reach it by such different routes. He [*i.e.* Darwin] starts from the present time and by a rigid process of induction argues that nature commenced her existing animal kingdom by the creation of some 4 or 5 forms, her vegetable one by about as many primary vegetable forms thousands of years ago. Such is the process by which the patient and laborious Saxon goes to work. The rapid thinking and impulsive Celt on the other hand, having caught sight of his theory in the distance, straightway bounds to prove by induction that it must be right. While the cautious Scotchman looks first at the one and then at the other and right or wrong thinks both have missed the mark and concludes that Moses is the profoundest Philosopher of the three since he is content to take things as he finds them and in one word declares all we know or are ever likely to know by saying *God Created*, without enquiring how".

# STRUCTURE AND EVOLUTION OF THE LEVANT AND NORTHERN AFRICA

By Dr. K. S. SANDFORD
University Museum, Oxford

THE following notes are an attempt to recapitulate the essential stages in the development of the southern side of the western Tethys and of the Mediterranean. They refer particularly to Leo Picard's publications, especially "Structure and Evolution of Palestine, with Comparative Notes on Neighbouring Countries"*, from the point of view of the geologist who has some familiarity with north African problems. Much that is still in doubt and much of local significance must inevitably be omitted; nevertheless a broad review of this type may be useful at the present juncture.

At the end of the Pre-Cambrian, Palestine lay on the borders of a high (Upper Algonkian) mountain range in which earlier mountains and varied rock types were welded into a mountain mass: this may be traced from Arabia through Sinai and the Red Sea Hills into Africa ("Arabo-Nubian mass"). Pre-Palæozoic denudation reduced the mountains to a lowland with seas lying on the west and north, the latter being identified with an east-west Palæozoic sea. Marine Cambrian beds are recorded on the mainland mass of north-west Africa and of western Asia, and from the Cambrian to the Cenozoic there were far-reaching transgressions across Mauritania, the Sahara, Libya and Egypt into the interior of Africa, across Palestine into Arabia.

During regressive phases, widespread continental beds were laid down over areas formerly marine. As there was continuous subaerial denudation and accumulation over the land areas, stratigraphy there is concerned largely with the interdigitation of continuous and discontinuous subaerial deposits, lagoonal and marine beds. The shore-line, continually shifting, was frequently indented: the sea and its lagoons ran far into deep bays between promontories on which subaerial processes continued. The advances of the epicontinental seas might therefore be called, as Picard suggests, ingressions rather than transgressions. The major promontories were broadly related to swells or structural undulations, the locations of which in northern Africa are plainly marked.

The continental beds consist for the most part of dune-sands and fluviatile quartz conglomerates: similar beds are now accumulating in the continental interiors of Arabia and northern Africa. Nubian Sandstone is an unfortunate term for these beds, in my opinion; Nubian facies expresses all that is desired: Nubia (in a broad sense) and lands to the south of it have probably been continental since the Pre-Cambrian.

Palæozoic transgressions (or ingressions) occurred in Palestine and adjoining territories in the Middle Cambrian, Ordovician, Silurian, Lower Devonian (?) and Lower Carboniferous (Sinai and on the Egyptian side of the Gulf of Suez): the Silurian left graptolite-bearing shales in Central Arabia.

In northern Africa the Palæozoic transgressions, Cambrian, Ordovician, Silurian, Lower-Upper Devonian, Lower Carboniferous seem to have come from the west rather than the north. The Silurian graptolite-bearing shales can be traced far into the interior, where they pass into sandstones. In western Asia, as in northern Africa, the Carboniferous seems to have witnessed final Palæozoic regression. The Triassic palæography of Palestine was nevertheless related to that of the Palæozoic, with a shelf sea, transgressive from the nearly Tethys, in the Lower-Middle Trias, followed by Upper Triassic uplift and continental beds.

The north-western corner of the African shield, with its Palæozoic blankets, was involved in Hercynean mountain building, and Triassic (or Permo-Triassic) red beds with salt mark a stage in the ensuing denudation: except for small patches of lagoonal beds, the unfolded continental platform seems to be devoid of Triassic rocks.

In Sinai and Palestine there was renewed transgression of a Jurassic sea shallowing eastward: locally there are thick Bajocian – Kimmeridgian beds following a Lower Jurassic (Liassic) continental phase. Moreover, the uppermost Jurassic (Portlandian) beds appear to be regressive-continental, a condition which was maintained until Wealden (Lebanon – Palestine), Albian (Syria), or Cenomanian (Eastern Sinai–Transjordan) transgression supervened. The 'facies of the Nubian Sandstone' predominated during the regressive and transgressive phases; there was extensive volcanic activity and probably fracture in the transition from the Jurassic to the Cretaceous.

There is a small exposure of marine Jurassic beds on the Egyptian side of the Gulf of Suez; otherwise they do not seem to be exposed in Egypt, Libya or the Sahara: some continental beds are known in Libya, and probably there are others. A new element is discernible however, namely, the Mesozoic sea of

* Structure and Evolution of Palestine: with Comparative Notes on Neighbouring Countries. By Leo Picard. (Bulletin of the Geological Department, Vol. 4, Nos. 2, 3, 4.) Pp. iv+134. (Jerusalem: Geological Department, Hebrew University, 1943.)

Barbary, where thick Jurassic sediments, mostly limestones, followed the Trias: they represent sedimentation in a deepening sea which seems to have transgressed southward on to the platform of the Sahara only locally (Saharan Atlas, Tripolitanian coast). The Jurassic development of Barbary and of the northern Saharan fringe therefore differed from that of the Levant in certain particulars; in both there were ingressions accompanied by thick limestones, and between them continental north Africa was probably dry land.

Much uniformity is to be observed in Cretaceous development. Aptian – Albian transgression appears from north Sinai across Palestine to the Lebanon; southern Sinai and Transjordan were still continental, but the sea penetrated into them in the Upper Cretaceous, in part only in the Upper Cenomanian: it does not seem to have invaded the Arabian Central mass. The Upper Cretaceous dolomite is thick in Palestine, in western Transjordan the beds are thin and sublittoral; the Senonian – Maestrichtian being phosphatic and including abundant cherts. There was Upper Cretaceous vulcanicity in Transjordan.

In north Africa transgression was widespread from Egypt to the Atlantic, giving rise to shales, marls and limestones, and penetrating to the continental interior. In Egypt the Lower Cretaceous is slightly exposed only in the north, the Upper Cretaceous Cenomanian and Turonian transgressed farther to the south, and the Senonian – Maestrichtian includes the most southerly outcrops. Their littoral phosphatic beds can be traced eastward into Sinai, Transjordan and Syria and westward across the Libyan desert. Nubian facies and lagoonal deposits were developed over the continental surfaces near and inland of the Cretaceous shores. The history of Cretaceous transgression was broadly similar in Egypt, Libya, and the northern Sahara.

Similar conditions also obtained over the southern (Saharan) part of Barbary; but in the northern part (Tell Atlas), bathyal (Tethys) sediments accumulated.

The passage from Cretaceous to Palæogene introduces a number of small but important changes. In Palestine and adjacent territories sediments were laid down in deep bays bounded by land swells (bituminous chalk series): vertical movements therefore gave rise to gaps and discordances in Danian, Eocene and Oligocene beds. In two great north African embayments, Egypt – Libyan desert and Sirtica, Lower Eocene chiefly nummulitic limestones followed the Cretaceous, though the conformity between them is not perfect, and in the Tertiary gulf of Sirtica the Lower Eocene rests on Palæozoic and Mesozoic continental deposits. The Middle and Upper Eocene seas retreated northward to such an extent that the Oligo-Miocene shore line ran from the region of Cairo roughly westward nearly to Tripoli: the regions of the great Cretaceous – Lower Eocene shelf seas were land once more, with continental deposits of Nubian facies and notable cobble beds made of Eocene cherts.

Farther west, in the Sahara, end-Cretaceous regression was final: there was no major Eocene transgressive sea but only shrinking Algerian – Tunisian and western Moroccan bays with their valuable Cretaceous – Eocene phosphatic limestones. This marked dissimilarity with the east is associated with the convulsion of the Tethyan geosyncline and the creation, in part, of the Atlas mountain system, of flysch and bathyal deposits, largely at the expense of the northern shield rocks and their blankets of Mesozoic sediments; the bathyal Mesozoic beds of the geosyncline itself were also involved.

The movements responsible for the Cretaceous – Eocene disconformities, local and highly variable in their magnitude and significance between Saharan Barbary and the Levant, are no doubt related to that convulsion, but they are epeirogenic discordances, as Picard points out, remote from the geosyncline, devoid of a flysch facies; and their influence, mainly pre-Eocene, may also account for many changes of Mesozoic facies, both marine and continental.

In Palestine the rhythm of up-and-down movements was interrupted by a short-lived Lower Miocene (Burdigalian) phase of tangential folding, immediately succeeded by renewed uplift, extensive fracturing, block-movements, and some volcanic activity. Still greater uplift followed in the Pontian and in pronounced form at the end of the Pliocene. Picard remarks that the last of these transferred the Burdigalian fold-ranges into upwarp arches and downwarp basins. There is much that points to the Burdigalian of the Levant marking a major orogenic break between Palæogene and Neogene, the varied and thick inland deposits of which may be related to those of Iraq and adjacent territories. Already in Miocene times the fractures induced the formation of graben which, with the folding troughs, formed inland basins. Miocene to Pleistocene cycles of sedimentation took place in these basins, the tectonics of which, owing to the plasticity of their salt and gypsum, are complicated and of peculiar individuality.

The last major fracture phase in Palestine occurred between the Old and Middle Pleistocene and was accompanied by thick and widespread basaltic flows which have preserved large areas of the old land surface: movement has not yet ended. The Quaternary deposits of Palestine are therefore a legacy of the Miocene, and in the several distinct basins, especially that of the Jordan, their history can be traced in considerable detail.

On the Palestinian coast marine Neogene ingressions (Vindobonian, Astian) formed narrow embayments: there was no longer deep transgression over Transjordan. On the whole the Neogene, and perhaps the Oligocene, marked a great regression, with minor oscillations.

It is difficult at present to give an entirely satisfactory review of the north African Neogene development because much of it is still open to debate. It is well known that a much broken area lies between the Gulf of Suez and the Nile valley, in which certainly three directions of faulting may be recognized, in which also folded structures are prominent. Various interpretations have been put upon them: space forbids adequate discussion of a considerable controversy. Perhaps all that is vital and not controversial can be put in a few sentences. Oligo-Miocene or Burdigalian deposits both here and as far as Cyrenaica chronicle primarily destruction of the land by subaerial denudation: some of the beds may be marine, some fluviatile, and there are doubtless gaps in the sequence. Middle and Upper Miocene beds are mainly shallow-water marine limestones and marls. There were important Oligo-Miocene or Miocene basalt flows and sills. A conservative view of the fractures east of the Nile to Sinai is that they owe their origin to movement of blocks, that some of them are pre-Miocene, and that these made way for Miocene ingression, as in the Gulf of Suez, but that some of them are post-Miocene. Folds, some of them spectacular, may be related to bending induced

by faulting, but from eastern Egypt to the Libyan desert there are marked undulations running north-east – south-west across the broadly longitudinal swells. These remarks may apply in modified form to Cyrenaica. Between the Nile and Cyrenaica the country does not seem, on the whole, to have been so severely broken. West of Suez along the Egyptian coast fracturing probably ended before the Pliocene, or in its earliest stages. There was a period of great volcanic activity, of Tertiary to Recent age, in the interior.

Pliocene beds lie unconformably upon various Tertiary rocks. Important ingressions and regressions took place within the Pliocene itself, especially in Egypt, followed by lesser marine oscillations, finally recessive, in the Pleistocene.

From these facts, it may be implied that north Africa felt the repercussions of the Neogene upheavals in the geosynclinal Tethys, and reacted to them in a distinctive and recognizable manner. In Barbary the final stages of mountain building were enacted, accompanied by the exclusion of the Neogene gulfs from among the major mountain elements of the Tell. It was a long process, which contrasts sharply with the peculiar Burdigalian folding phase recognized in Palestine.

# OBITUARIES

## His Grace the Archbishop of Canterbury

THE death on October 26 of Dr. William Temple, Archbishop of Canterbury, was a sad blow not only to his intimates and his Church, but also to the rest of the nation and, indeed, the whole world. In the short two years of his primacy, Dr. Temple had earned and gained a unique place in the affection and regard of the people. Although erudite he was no dreary scholar; although deeply religious he was not sanctimonious; although a man of high standards he was charitable to others.

Much has been made in recent years of 'the conflict between science and religion', and the friction of this conflict has engendered more heat than light. The difficulty has been that so few men of science have understood religion, and most churchmen have been ignorant of science. William Temple bridged this intellectual gap and, perhaps even more important, bridged the gap in social intercourse. His years at Manchester and York gave him many opportunities to make contact with men and scientific organizations, and he made the most of them. His appreciation of science was well disclosed in his sermon in Manchester Cathedral before the Victoria University of Manchester during its jubilee celebrations in 1929. Then he emphasized the essential need for universities to foster scientific research alongside scientific training.

It was, however, since his translation to Canterbury in 1942 that Dr. Temple took the most active interest in the field of the social sciences. Especially valued was his help in the work of the Central Council for Health Education, of which he was president. His influence and prestige were invaluable, but he was no mere letter-heading. His conduct of the meetings of the Council was a model of chairmanship, and many passages were eased by his urbane humour and kindly wit.

Dr. Temple was truly a spiritual leader, but in the more everyday practical problems of human society he also took a leading part. He got, and helped others to get, at the roots of certain evils of social and industrial life. He realized that here were problems of the spirit, for the understanding of which a widespread general education is necessary before any attempt can be made at their solution. He held an important position in the Workers' Educational Association, being its president for sixteen years (1908–24). His very practical philosophy comes out in all his well-known books, but perhaps more than elsewhere in his Gifford Lectures of 1932–33 and 1933–34 on "Nature, God and Man", in which he pleaded for dialectical realism as opposed to the dialectical materialism of Marx. Onwards from then, and especially at the Malvern Conference, his sermons, addresses and writings convinced a wide public that the Church is not concerned with "another world" but is a strong social force in this. As *The Times* said: "he was a philosopher whose mind had been deeply given not only to classical studies but also to the problems of current thought".

Born in a bishop's palace, and educated at Rugby and Oxford, Dr. Temple yet was one of the common people. He towered above the rest of us, yet neither appeared himself to be aware of the fact nor did he make his fellows unduly conscious of it. Truly he was a leader of men.

## Dr. Dorothy Ashworth

DR. DOROTHY ASHWORTH, whose untimely death at the age of thirty-six occurred on October 4, was, we had assumed, one of our coming plant pathologists. Her work on plant rusts began at the Royal Holloway College after she graduated from there in 1929, and it was during her second postgraduate year that Dr. Holden, on a visit to the College, saw and appreciated her skilful and immaculate technique in the isolation of sporidia and her inoculations with single sporidia. She was, in the following year, awarded a research studentship at University College, Nottingham, and continued the work in Prof. Holden's laboratory. The next year found her working in the Cryptogamic Laboratory of the University of Manchester, and from there she passed to the laboratory of the Royal Horticultural Society's Gardens at Wisley as assistant mycologist. Her work has been characterized throughout by exceptional thoroughness and sincerity. Her modest, unassuming manner masked a critical approach, sound judgment and a firm opinion. Her composed demeanour covered a meticulous care of the material in her charge and a constant watchfulness. There was no impatience for results, no haste to publish. Her attitude was simply that of a student seeking the truth. Science can ill spare such a faithful servant.

E. M. BLACKWELL.

DR. ASHWORTH joined the staff of the Royal Horticultural Society at Wisley Laboratory in the summer of 1935 as assistant to the mycologist. Before this her work had been concerned with pure research on various rust fungi, but she quickly adapted herself to the practical problems of horticultural plant diseases, and besides continuing valuable studies on various fungus parasites, notably the *Antirrhinum* rust fungus, *Puccinia Antirrhini*, rendered valuable assistance in the experiments on methods of control of diseases in certain ornamental and crop plants.

She was an ideal research worker, with a highly developed scientific and practical outlook, skilful, industrious and with a distinct flair for laying out and arranging experiments. Her technique was meticulous and her caution in studying data and reaching conclusions made for the utmost reliability.

At Wisley the very varied advisory and routine work precludes full-time attention to long-range research problems, but Dr. Ashworth investigated many diseases, such as a rust of rhododendrons, *Chrysomyxa Rhododendri*, the winter killing of wall-flowers, etc., and in collaboration with the writer was each year engaged in various field experiments on the control of various diseases of fruit, vegetables and flowers, for example, blight on outdoor tomatoes, club root of brassicas. In all this the standard of her work was always of the highest.

In 1943 she began the most important problem of her career, for which she was ideally fitted by training and inclination. The Dominion botanist of Canada approached the Council of the Royal Horticultural Society with the request that the very large collection of *Berberis* species and hybrids at Wisley be used for testing their susceptibility to black stem rust of wheat, as this knowledge was important in considering the importation of such plants in the Dominion. Accepting this work, she quickly made progress and recorded infection of some twelve species of *Berberis* by the wheat rust fungus once considered to be restricted only to *B. vulgaris*. Her special knowledge regarding the germination of teleutospores and sporidial infection, and her instinct for applying the correct technique in this kind of work, will be missed.

Visitors to the Wisley Laboratory will remember her engaging manner, and the many horticulturists who knew her will regret this loss to the science of horticultural plant pathology.

D. E. GREEN.

# NEWS and VIEWS

## Nobel Prize for Physiology and Medicine for 1944: Prof. J. Erlanger and Dr. H. S. Gasser

THEIR many friends on this side of the Atlantic will have been delighted to hear of the award of the Nobel Prize for Physiology and Medicine for 1944 to Dr. Joseph Erlanger, formerly professor of physiology at Washington University, St. Louis, and Dr. Herbert S. Gasser, director of the Rockefeller Institute, New York. The award recognizes a fundamental advance in the analysis of the nervous system. Nowadays, amplifiers and cathode ray oscillographs are part of the standard equipment of the neurophysiologist; the passage of the waves of activity in the peripheral nerve fibres can be timed to the nearest ten thousandth of a second and followed through the networks of the central nervous system with the same accuracy. It is to Gasser and Erlanger that we owe the introduction of this precision. They were the first to make effective application of new electrical techniques, after the War of 1914–18. By 1922 their cathode ray records had shown an unexpected complexity in the 'action potential' of a nerve trunk, and soon after they were able to prove that this was due to different groups of nerve fibres conducting at different rates.

An analysis of the groups in various nerves held out the hope of a close correlation between the function of the nerve fibre and its size and rate of conduction. A rigid correlation cannot be made, but the careful search for it has advanced our knowledge in many fields; for example, that of the mechanism of pain, of reflex activity and of inhibition. Erlanger and Gasser's work has inspired a large and active school of neurophysiologists to whom its precision and critical insight have set a very high standard. Their collaboration at St. Louis was cut short by Dr. Gasser's appointment as professor of physiology at Cornell University, but was renewed in 1936 in their Johnson Lectures on the "Electrical Signs of Nervous Activity". These lectures form an impressive account of the development of a new branch of neurological research.

## *The Lancet*: Retirement of Dr. Egbert Morland

DR. EGBERT MORLAND, editor of *The Lancet*, has retired. Though thirty of his seventy years have been given to medical journalism, this was the third of his careers. Of a Quaker family, he took his B.Sc.(Lond.) from Owens College with first-class honours, and distinguished himself at St. Bartholomew's Hospital Medical College, winning the M.B. gold medal in physiology. But the series of junior hospital posts that should have led to consultant practice ended when, like many another house-physician of those days, he developed tuberculosis. In Switzerland he embarked on a second career: he took the Swiss federal diploma and the M.D. Berne, settled in Arosa, and became an expert in the disease he had overcome, writing a prize essay on sanatorium construction and many papers on tuberculin. The contentment of his trilingual practice, however, was destroyed in 1914. After relief work on the Marne, he came to London and called at *The Lancet*. The editor, Squire Sprigge, asked him to remain as his assistant, and in 1937 he succeeded to the editorial chair.

Dr. Morland's experience and talents alike fitted him to conduct a medical journal of international scope. He combines a taste for detail with a flair for essentials, and innumerable contributors have been grateful for his drastic sub-editing of their papers. By concentrating on the needs of the reader he has played no small part in bringing about the improvement evident of late years in the presentation of medical data. His editorial columns have been enlivened by an eager mind, always ready to reconsider even the most venerable hypothesis. Likewise his intense interest in social and medical reforms has arisen from the needs of people, never from theories. Having found *The Lancet* humane, he leaves it human. He was elected a fellow of the Royal College of Surgeons in 1936 and of the Royal College of Physicians in 1941.

## Prof. A. G. Pugsley, O.B.E.

DR. A. G. PUGSLEY has been appointed to the chair of civil engineering in the University of Bristol formerly held by Prof. J. F. Baker, who was appointed in 1943 to succeed Prof. C. E. Inglis at Cambridge. Prof. Pugsley was educated at Rutlish School and Battersea Polytechnic, and graduated with first-class honours in engineering in the University of London in 1923. After serving as a student-apprentice in civil engineering at the Royal Arsenal, Woolwich, he was appointed a junior technical officer for design and research work at the Royal Aircraft Establishment Works, Cardington. In 1931 he transferred to the Royal Aircraft Establishment as a scientific and technical officer, where he is now the head of the structural and mechanical engineering department. In 1938 he was awarded the degree of D.Sc. of the University of London. He is a member of several sub-committees of the Aeronautical Research Committee and of the Ministry of Production. Dr. Pugsley has made notable contributions to engineering science, particularly in connexion with the structural design of aircraft and airworthiness, and the aero-elastic problems involved.

## British Non-Ferrous Metals Research Association: Mr. G. L. Bailey

THE British Non-Ferrous Metals Research Association has appointed Mr. G. L. Bailey as director to succeed Dr. H. Moore who has retired (see *Nature*, October 14, p. 482). Mr. Bailey graduated in metallurgy at the University of Birmingham, where he was awarded the degree of M.Sc. in 1922 after completing two years research work. During 1922–30 he was on the staff of the Research Department, Woolwich, where he carried out research on a variety of problems in non-ferrous metallurgy. During this period his most notable work was on the casting of 70/30 brass ingots for subsequent rolling, the results of which were published in association with Dr. R. Genders by the British Non-Ferrous Metals Research Association in a monograph "The Casting of Brass Ingots".

In 1930 Mr. Bailey resigned from the Research Department at Woolwich to accept the appointment of development officer of the British Non-Ferrous Metals Research Association. In this post he was responsible for fostering the application of the results of the Association's researches in industry. He played, however, a wider part in the Association's organization and in January 1942 became deputy director. Mr. Bailey is a vice-president of the Institute of Metals and chairman of the London Local Section of that body.

## Lister Memorial Lecture of the Society of Chemical Industry

THE first Lister Memorial Lecture of the Society of Chemical Industry will be delivered by Sir Alexander Fleming in the Anatomy Lecture Theatre, University of Edinburgh, on November 9 at 5.30 p.m. The subject of the address will be "Antiseptics". Under the auspices of the Society of Chemical Industry, endowed memorial lectures have recently been founded in different parts of Great Britain to perpetuate the memory of scientific men and industrialists whose work has assisted in building up the chemical industry. The name of the late Lord Lister has been chosen for commemoration in the Edinburgh and East of Scotland Section of the Society on account of his connexion with Edinburgh and because of the stimulating effect his revolutionary medical methods had on the growth of the fine chemical industry in Great Britain. The endowment has been the gift of two Edinburgh pharmaceutical chemical manufacturers, Messrs. J. F. Macfarlan and Co. and Messrs. T. and H. Smith, Ltd. The lecture will be delivered every four or five years in Edinburgh, Aberdeen or St. Andrews.

## Research on Tsetse Fly and Disease

THE Secretary of State for the Colonies has appointed a committee to consider and advise on the co-ordination of action, including research, directed against human and animal trypanosomiasis, and, in particular, against the tsetse fly as the chief vector. The committee, on which the Dominions Office and the Sudan Government are represented, will report from time to time to the Secretary of State for the Colonies, and on all matters affecting research its recommendations will be referred to the Colonial Research Committee for comment and advice before submission to him.

The committee is composed as follows: Mr. G. H. Creasy (chairman), Colonial Office; Sir Robert Archibald, representative of the Sudan Government; Prof. P. A. Buxton, London School of Hygiene and Tropical Medicine; Dr. H. Lyndhurst Duke, lately director of the Human Trypanosomiasis Institute in Uganda, and chairman of the League of Nations Sleeping Sickness Committee; Mr. S. A. Goulborn, Dominions Office; Prof. I. M. Heilbron, Imperial College of Science and Technology; Dr. E. M. Lourie, Liverpool School of Tropical Medicine; Sir Guy Marshall; Dr. S. A. Neave, director of the Imperial Institute of Entomology; Mr. G. F. Seel, Colonial Office; Dr. A. G. H. Smart, medical adviser to the Secretary of State for the Colonies; Mr. John Smith, adviser on animal health to the Secretary of State for the Colonies; Dr. H. A. Tempany, agricultural adviser to the Secretary of State for the Colonies; and Mr. C. W. F. Footman (secretary), Colonial Office.

## Cinemicrography

Two complementary papers dealing with cinemicrography were given at a meeting of the Association for Scientific Photography on October 14. Mr. H. Emmett described the apparatus used in one of the I.C.I. research laboratories, consisting of a petrological microscope, above which is supported the cine camera without its lens, while the microscope is also used without the usual eyepiece, but with a viewing attachment to enable the image to be kept under observation while being filmed. Focus on the film is ensured by inserting a piece of ground glass in the gate and balancing this image with the one seen in the viewing eyepiece; careful centring of the light is obviously of first importance. A 9·5 mm. camera was used connected through a belt drive to an electrically controlled gramophone motor which enables exposures to be taken at known intervals. Mr. Emmett showed films illustrating crystal growth, such as the change in crystalline form induced by the presence of impurities, the allotropic change in acicular crystals of ammonium nitrate which can take place on lowering the temperature, and the concentration gradient around a crystal during growth.

The second paper, by Mr. R. McV. Weston, entitled "Cinemicrography in Biological Research" dealt with similar problems but described a more elaborate

apparatus for higher power micrography and using a 16 mm. Cine-Kodak Special camera to record the images. Owing to the employment of living specimens, a rotating sector shutter was used to prevent overheating and the whole of the microscope stage was enclosed in an incubator, the necessary controls being outside. The heating elements were two 30-watt carbon filament lamps shielded to prevent direct rays reaching the object and a chloroform-mercury thermostat next to it. As in the first apparatus, the light was provided by a 100 c.p. Pointolite lamp. Mr. Weston showed a film of the movement of the leucocytes among the red corpuscles of the blood, and higher magnifications showed very clearly the triple nuclei.

## Electrical Accidents

IN a memorandum (*J. Inst. Elec. Eng.*, **91**, Pt. I, No. 43; July 1944) which assesses electrical accidents in relation to other accidents, and includes an appraisement of some electrical fire statistics, the published statistics of fatal accidents in Great Britain are analysed and the proportion of those of electrical origin are assessed in their relationship to the whole with special consideration of those occurring on domestic premises. Certain statistics concerning fires attributed to electrical causes in both domestic and industrial premises are studied, and the contributing factors are analysed in the order of their importance. It is concluded that electrical accidents have shown no significant increase in relation to the increased use of electricity. The number of fatal accidents due to defective installations tends towards a very low figure; but increasing attention should be given to the quality and maintenance of flexible connexions of the portable appliances employed in domestic situations and to the design and maintenance of the appliances themselves.

Statistics on the incidence of electrically caused fires are not adequate and do not give precise information on the primary causes of such fires. It appears that some 35 per cent of all fires attributed to electrical causes arise from faults in the fixed installations; but of the total fires attended, only 1·7–3·5 per cent are attributable to installation defects. The figure for domestic and similar premises is deemed to be lower than this, while the effect of improved techniques, the elimination of D.C. supplies, the use of new materials, and the provision of installations integrally planned in relation to other services in the structure, will all tend to produce a further reduction in the risks. A study of the commoner causes of fires indicates that, in addition to an expected decline in electrically caused fires in proportion to the utilization of electricity, a substantial decrease in the total number of fires is likely to occur as electricity supplants other fuels as a means for space-heating, water-heating and cooking.

## Royal Society of Edinburgh : New Officers

AT the annual meeting of the Royal Society of Edinburgh held on October 23, the following officers were elected: *President*, Sir William Wright Smith; *Vice-Presidents*, Prof. T. H. Milroy, Sir John Boyd Orr, Dr. A. W. Greenwood, Prof. E. Hindle, Dr. D. Russell, Prof. R. J. D. Graham; *General Secretary*, Prof. J. P. Kendall; *Secretaries to Ordinary Meetings*, Prof. W. M. H. Greaves, Prof. A. Holmes; *Treasurer*, Sir E. M. Wedderburn; *Curator of Library and Museum*, Dr. J. E. Mackenzie; *Councillors*, Mr. Stanley Cursiter, Dr. Douglas Guthrie, Prof. J. W. Heslop Harrison, Mr. A. W. Young, Prof. E. T. Copson, Lieut.-Colonel W. F. Harvey, Prof. A. E. Trueman, Prof. J. Walton, Prof. T. Alty, Mr. J. Morrison Caie, Sir Robert Muir, Sir David K. Murray.

## Announcements

THE Joint Committee of the Royal Physical Society, the Royal Scottish Geographical Society and the Royal Society of Edinburgh has awarded the Dr. W. S. Bruce Memorial Prize (1944) to Lieut. T. H. Manning, R.C.N.V.R., for his valuable survey and biological work during 1931–39 in Iceland, Lapland, Southampton Island, Hudson Bay and at Foxe Basin (1936–39).

AFTER the liberation of Paris, the secretary of the British Association was enabled, through the courtesy of M. Louis Rapkine, of the Mission scientifique française en Grande-Bretagne, to address a letter of goodwill to Prof. A. Verne, secretary-general of the French Association for the Advancement of Science. A message of greeting and hope for the early renewal of active relations between the two Associations has now been received by the Council of the British Association from Prof. Verne on behalf of the president and bureau of the French Association.

DR. A. N. MAY, lecturer in physics at King's College, University of London, has been appointed as from October 1 to the University readership in physics tenable at King's College. Since 1942 Dr. May has been on war service with the Department of Scientific and Industrial Research.

The following doctorates have been conferred by the University of London: D.Sc. on C. N. Acharya, Rothamsted Experimental Station; A. L. Green, King's College; Miss L. E. Hawker, Imperial College of Science and Technology. D.Sc.(Econ.) on B. R. Misra, London School of Economics.

THE following appointments have recently been made by the Colonial Office: R. J. Dewar and J. G. McQuillen, to be assistant conservators of forests, Nigeria; K. W. Aspinall, to be veterinary officer, Tanganyika; J. J. Steyn, to be entomologist, Uganda; J. N. Clothier and R. H. Fraser, agricultural officers, Northern Rhodesia, to be senior agricultural officers, Northern Rhodesia; D. F. Macpherson, veterinary officer, Kenya, to be senior veterinary officer, Kenya.

AN exhibition of historic scientific instruments and books, drawn from the collection which Mr. R. S. Whipple is presenting to the University of Cambridge, will be held in the East Room of the Old Schools during November 4–11. The exhibition will be opened by Sir Henry Dale, president of the Royal Society, on November 4 at 2.45 p.m., and will remain open on weekdays from 10 a.m. to 5 p.m. Admission is free. It is intended that the Whipple Collection shall form the nucleus of a museum of the history of science in the University.

PROF. J. HADAMARD will be unable to give the lecture announced for the annual general meeting of the London Mathematical Society on November 16. Prof. S. Mandelbrojt will give a lecture "On the Regularization of Sequences". It is hoped that Prof. Hadamard may be able to lecture at a later meeting.

## Fetuin, a New Globulin Isolated from Serum

DURING a study on the fractionation of serum with ammonium sulphate, I thought it worth while to try whether some of the serum proteins could be isolated more easily from the serum of a newly born animal. Serum from calves not more than two weeks old was used for these fractionation experiments, which immediately indicated a pronounced difference between the serum from the calf and that from the cow. Ultracentrifugal examination of the different fractions revealed the presence of large amounts of a globulin with the sedimentation constant, $s_{20}$, of the order $3S$ ($1S$ (Svedberg) $= 1 \times 10^{-13}$ C.G.S.) as compared with the normal $s_{20} \sim 7S$ for serum globulin. The main part of the new protein was precipitated between the salt concentration limits 0·37 and 0·45 saturated ammonium sulphate. It was purified further by fractionation with ammonium sulphate and centrifugation in a high-speed air-driven centrifuge. Molecular weight determination gave a value of the order 50,000[1].

Experiments with serum from calves of different ages have shown that the amount of this globulin has its highest value in the newly born calf, and decreases with time. In the adult cow, its presence may be demonstrated in the fractions which correspond to those from the newly born calf where the new globulin is the predominant component. It seems reasonable to assume that the concentration of the new protein shows its maximum value in the fœtus and that it is in some way associated with the period when the greatest building and development of the animal takes place. I therefore propose that this new protein be called 'fetuin'. The name is derived from the Latin name for fœtus, namely, *fetus*.

Later experiments with fœtal sera from cow and sheep have shown that the 'total globulin' obtained from these liquids mainly consists of fetuin, whereas the presence of ordinary globulin with $s_{20} \sim 7S$ can just be demonstrated. Serum from human umbilical blood was also examined, but its contents of fetuin was only a few per cent. The same serum, however, contained considerable amounts of globulin with $s_{20} \sim 7S$. A similar result was obtained with rabbit fœtal serum, whereas foal serum behaved similarly to that from the calf.

The same grouping of the species (cow, horse and sheep on one side, and man and rabbit on the other) is found in one of their immunological properties. Thus placental transmission of antibodies takes place in the latter group, while the newly born animal of the former group receives its antibodies with the colostrum, when it is suckled for the first time (see ref. 2). There is also a distinct difference between the two groups in the construction of the placenta. In the case of ruminants, the placenta consists of three layers of cells, whereas in rodents and man the maternal blood is separated from the fœtal by only a single layer of cells.

It is still an open question whether or not fetuin is generally present in embryonic serum. In this connexion, it is of interest to note that Svedberg and Andersson[3] several years ago, in an unpublished investigation, found that no component with $s_{20} \sim 7S$ was present in serum from chicken embryo after 11–15 days incubation. The 'albumin peak' in the sedimentation diagram, however, was very asymmetrical and gave comparatively low values for the sedimentation constant. The low value for $s_{20}$ in this case may perhaps be explained by the possible presence of fetuin in the embryonic serum. After 18 days of incubation the globulin amounted to 22 per cent of the protein, and the 'albumin peak' had become more symmetrical.

Differences between hæmoglobins from adult and from fœtal blood have been reported from time to time, and it was generally supposed that they were to be found in the protein moiety of the molecule. Several years ago, G. S. Adair[4] found that maternal and fœtal hæmoglobin from sheep could be easily distinguished in electrophoresis. Quite recently, Wyman *et al.*[5] have demonstrated great differences in the solubility of maternal and fœtal hæmoglobin from the cow. At the same time, Andersch *et al.*[6] showed that the electrophoretic mobility is not the same for hæmoglobin from a newly born infant as that from an adult. The two sedimentation constants were also unlike ($s_{20} = 2·5S$ for the infant and $4·7S$ for the adult).

It is thus evident that in the case of the respiratory proteins and also in the serum proteins, great differences exist between their properties in the embryonic state and in the adult animal. This investigation is being continued, and details will be published elsewhere.

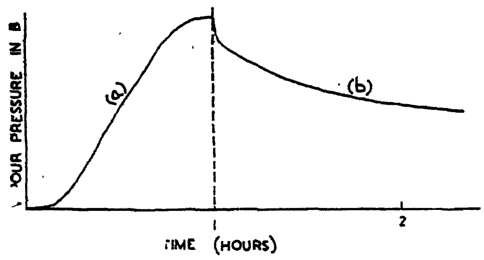
## Permeability of Keratin Membranes

BARRER[1] has suggested that the diffusion of vapours through media in which sorption and swelling occur are governed by a generalized form of Frick's Law, in which the diffusion constant is a function of the vapour concentration in the specimen.

Recent measurements in these laboratories of the diffusion constant of water vapour in keratin have provided an example of this phenomenon. At water contents below 6 per cent on the dry weight, the diffusion constant becomes extremely small in comparison with its value at higher concentrations.

This property of keratin may be demonstrated very simply as follows. Two compartments $A$ and $B$, separated by a film of horn a few thousandths of an inch thick, are both evacuated. Then on introducing water vapour into $A$ the subsequent rise in pressure in $B$ follows Curve $a$. The diffusion is slow until the film acquires a water content of about 6 per cent throughout, when a rapid increase in transport occurs, despite the decreasing pressure difference across the membrane, because of the large increase in the diffusion constant.

If, after equilibrium is attained, the water vapour is rapidly removed from $A$, the fall in pressure in $B$



becomes extremely slow after an initial rapid drop (Curve $b$). This is clearly due to a decrease in the water content on the side of the film adjacent to $A$, to a value below 6 per cent, which opposes the attempt to reduce the pressure in $B$ by the rapid evacuation of $A$.

This phenomenon may be common to all such absorbing films. Sir Charles Martin informs me that attempts to increase the rate of evaporation of liquid water through a collodion film by forced air circulation always lead to a decrease in the rate of evaporation as compared with that in still air.

## Variations in the After-Glow Brightness of Active Nitrogen Under Varied Experimental Conditions

LORD RAYLEIGH, in a remarkable series of experiments, has studied photometrically the variations in the after-glow brightness of active nitrogen under varied experimental conditions. The results are of extreme importance in testing the various theories of active nitrogen. In the present note, some of these results will be considered in the light of the hypothesis recently proposed by me[1,2], namely, that active nitrogen is simply the ionized nitrogen molecule in the $N_2{+}\,(X')$ state produced by the discharge. If the walls of the vessel are suitably 'conditioned' to prevent the surface from acting as catalyst, the recombination of the positive ions with electrons proceeds mainly in the volume of the gas by a three-body collision process in which neutral nitrogen molecules act as the third body.

The experimental results discussed are as follow:

(1) The intensity of the glow in a vessel in which the active material is lost largely on the walls of the vessel falls exponentially with time $t$; the time required for the intensity, at any stage, to fall to its half-value is constant[3]. This is a characteristic of a unimolecular reaction. (The walls of the experimental vessel were 'poisoned' with Apiezon oil.)

(2) The intensity of the glow in a vessel in which the active material is lost mainly in the volume of the enclosing vessel varies inversely as $t^2$. This is a characteristic of a bimolecular reaction[4]. (The walls of the vessel in this case were coated with metaphosphoric or strong sulphuric acid to prevent surface reaction.)

(3) If the glowing gas is compressed, the intensity of the glow increases as the cube of the concentration[5]. This is a characteristic of a termolecular reaction.

(4) If the temperature of the glowing gas be lowered keeping the pressure constant, then, making allowance for increase of intensity due to increased concentration, the reaction-rate is found to have a negative temperature coefficient; it increases with the decrease of temperature[6].

To explain (1) we note that the recombination on the walls proceeds as follows. The electrons, on account of their higher velocity (due to smaller mass and to higher 'temperature'), arrive first on the surface (the 'poisoned' parts of it) and remain there as surface charge. The positive ions then arrive and become neutralized, giving up the energy of recombination to the glass walls. The poisoned or active parts of the glass thus play the part of the third body. The reaction-rate at any instant is obviously proportional to the active area and to the number of positive ions colliding with it per second. Since the active area remains constant, the number of recombinations is simply proportional to the rate at which the positive ions collide with the wall per second, and this in its turn is proportional to the density of $N_2{+}$ ions in the volume. The positive ion density and the reaction-rate thus fall exponentially with time, which gives the law of decay for a unimolecular reaction.

To explain (2) we recall that according to J. J. Thomson[7] the coefficient of recombination of electrons and ions ($\alpha$) by three-body collision is given by $\pi d^3u/\lambda$, where $d = 2e^2/3kT$ is the minimum distance of approach for the electron and the ion for effective three-body collision, $T$ is the electron temperature, $u$ the mean velocity of agitation of the electrons and $\lambda$ the mean free path—or rather, the mean energy free path—of the electrons. Now, the reaction-rate in the volume (temperature and pressure remaining constant) is given by $\alpha n^2$, where $n$ is the electron or positive ion density, assuming the two to be the same. From the expression for $\alpha$, we note that it is independent of $n$. The reaction-rate at any instant is thus proportional to $n^2$ and this explains the observed characteristic of the bimolecular reaction.

To explain (3), note that the reaction-rate $\alpha n^2$ is equal to $(\pi d^3u)n^2/\lambda$. When the glowing gas is compressed as a whole, the electron-ion concentration $n$ varies directly, and the energy free path $\lambda$ varies inversely, as the pressure. The reaction-rate, and hence the brightness of the glow, increases as the cube of the compression, which is a characteristic of a termolecular reaction.

To explain the negative temperature coefficient (4), note that in the expression for $\alpha$, $\lambda$ is independent of $T$, $d$ varies inversely as $T$ and $u$ varies directly as $\sqrt{T}$. $\alpha$ and, therefore, the reaction-rate, will vary as $T^{-5/2}$ (the concentration remaining constant). The hypothesis therefore predicts a negative temperature coefficient of the reaction-rate, as observed by Rayleigh. The calculated coefficient, however, appears to be much higher than the observed coefficient $T^{-0{\cdot}64}$. (In Rayleigh's experiment a part of the observation vessel—a tube attached to it—was cooled while the pressure remained constant. The increase of intensity due to increased concentration was allowed for in computing the coefficient. The observed coefficient was for the extreme range of temperature investigated, 90°–373° Abs.)

The discrepancy is explained if it is remembered that the temperature $T$ in the expression for $\alpha$ refers to the electron temperature and not to the molecular temperature. It is the latter temperature, however,

that was used in computing the coefficient; we do not know how the electrons in the observation tube were affected by the temperature variation of the medium surrounding it. It can, however, be safely assumed that on account of the high initial value of the electron temperature, its percentage variation was much less than the percentage variation of molecular temperature. The temperature coefficient computed by taking the molecular temperature is therefore necessarily smaller than the true coefficient. (It is to be remembered that J. J. Thomson's expression for $\alpha$ has not been tested for the pressures such as are ordinarily encountered in discharge tubes, and it is doubtful if the formula is strictly applicable to such cases, particularly because of the uncertainty regarding the energy free path $\lambda$. Nevertheless, the formula can be assumed to give, at least qualitatively, the nature of the variation of $\alpha$ with temperature, pressure and concentration).

## Borax as a Standard Buffer Solution

USERS of glass electrodes frequently require for purposes of standardization an easily prepared buffer solution in the region of $p$H 9, and use is generally made of an $M/20$ solution of A.R. borax, which according to tables[1] has a value of 9·23 at 20° C.

In the investigation of small errors in glass electrodes, it was found that the $M/20$ borax solution gave results which were invariably lower than the accepted values by about $p$H 0·05, and it was thought that these irregular results should be investigated as other workers might find similar difficulties in correlating data.

Samples of A.R. grade borax, made by reputable manufacturers, were first used, but it was found that when the solutions were prepared under the same conditions the results were uniformly low, indicating that the irregular results were not apparently due to methods of preparation of the material.

It has been stated[2] that $M/20$ borax solution has a $p$H value of 9·18 at 25° C. when the salt is treated so that it has the correct state of hydration, and as a check on this point a sample of borax was dehydrated to avoid errors of hydration. The $p$H value of an $M/20$ solution of the salt so prepared was $9{\cdot}13_2$ ($9{\cdot}17_2$ at 20° C.), which is still below the correct value.

A second sample was now prepared by dissolving the salt in boiling water to which sodium hydroxide was added to neutralize any possible traces of free boric acid. The salt was recrystallized from this solution and again recrystallized twice from distilled water. The product of each crystallization was filtered under vacuum and washed with distilled water. The final product was dried between filter paper in the air. A solution $M/20$ in strength was used for the test.

All the $M/20$ solutions were prepared from distilled water boiled in a 'Pyrex' flask and cooled with a soda-lime tube absorber for carbon dioxide. The $p$H measurements were made with hydrogen and calomel electrodes kept at constant temperature for 24 hours previous to the tests. Under these conditions the calomel cell has been found to give potentials in agreement with those given by Michaelis[3], and as a check an $M/20$ potassium hydrogen phthalate solution ($p$H 3·97) was tested. This showed the calomel cell had a potential correct to within 0·2 millivolt of Michaelis' values, and all readings of the various tests on the borax solutions were steady to 0·2 millivolt.

| Hydrogen electrode ° C. | Calomel electrode ° C. | E.M.F. mV. | $p$H | $p$H reduced to 20° C. |
|---|---|---|---|---|
| 20·2 | 20·5 | 782·6 | $9{\cdot}18_2$ | $9{\cdot}18_0$ |
| 20·8 | 21·2 | 782·6 | $9{\cdot}17_0$ | $9{\cdot}17_6$ |
| 21·0 | 21·2 | 782·8 | $9{\cdot}17_7$ | $9{\cdot}17_5$ |

From a long series of tests extending over several years, it has been found that the temperature coefficient of the $M/20$ solution of borax as given by Walbum[4] is quite correct even though the absolute $p$H value differs from his figures somewhat.

The $p$H values at 20° C. are computed on the basis of Walbum's figures, and rounding them off to the nearest $p$H 0·01, which is the limit of accuracy of ordinary $p$H measurements, it would seem that a value of 9·18 for an $M/20$ solution of $Na_2B_4O_7 . 10\,H_2O$ made up with carbon dioxide-free distilled water represents the more correct figure than 9·23 usually given.

It is difficult to offer any explanation of the discrepancy, since the original figures given by Walbum were presumably made with a hydrogen electrode. The value of 9·18 at 25° C. quoted by Hitchcock and Taylor[1] may have been based on a value of $p$H $4{\cdot}00_5$ for $M/20$ potassium hydrogen phthalate. Reducing their figure to the more usual value of 3·97, this gives 9·15, which is still $p$H 0·02 above the value usually found, a small but very definite discrepancy. It would be interesting to learn other workers' opinions on this point.

## Identification of the Montmorillonite Group of Minerals by X-Rays

THIS group of clay minerals (referred to hereafter for brevity simply as "montmorillonite"), which is often found in soil clays, fuller's earth and bentonite, is characterized by the variation of the position of the basal reflexion, on an X-ray powder or aggregate diagram, from about 10 to about 18 A., according to the state of hydration[1]. The minerals of the group are notoriously difficult to identify positively from a single X-ray diagram because ($a$) the line at 14 A., which is given by montmorillonite in a normal state of hydration, is liable to be confused with a basal

reflexion from chlorite or vermiculite, both of which might occur in soil clays; and (*b*) the basal reflexion may be diffuse, due to the simultaneous occurrence, in the crystallites, of two or more different basal spacings.

The former difficulty has been mentioned by Nagelschmidt[2], who recommends taking photographs of the clay at different stages of hydration, as a means of surmounting it; and the latter has been discussed in several papers by Jackson and co-workers[3], who have recommended a special procedure for the controlled hydration of montmorillonite, which they claim ensures a sharp reflexion at about 16 A. If these recommendations are to be followed, the procedure necessary for the mere identification of montmorillonite in clays will clearly be complicated and time-consuming.

For this reason, it seems worth while to direct attention here to a very simple and apparently quite unambiguous method which I have been using for some time for the purpose. It depends on the observation (made during some as yet unpublished research on the effect of absorption of alcohols on the montmorillonite lattice) that when montmorillonite is treated with glycerol, a very sharp and intense first-order basal reflexion is obtained at about 17·7 A., as well as a number of higher orders. The line at 17·7 A., being well separated from any lines due to other likely minerals, is very suitable for identification. All that is necessary is to add glycerol to a clay suspension at the rate of about one drop to each 80 mgm. of clay, and then evaporate to dryness. The latter operation may safely be completed on a steam bath or in a desiccator. This technique may be combined with Nagelschmidt's aggregate technique[4] by adding the right amount of glycerol to the clay suspension which is to be used for forming the aggregate.

From tests which I have carried out, it appears that the following advantages may be claimed for this method.

(1) *Wide applicability*. The method has been tried so far on montmorillonites from fuller's earth and bentonite, on nontronite, on Hector clay (octophyllite montmorillonite), and on a number of soil clays containing montmorillonite, and has given essentially the same result in all cases, at any rate so far as the first order of the basal reflexion is concerned. The ratios of the intensities of the different orders of the basal reflexion probably vary somewhat in the different types of montmorillonite minerals; but this is not very important from the present point of view.

(2) *Great sensitivity*. In a test to discover the minimum quantity of montmorillonite in a mixture which can be detected by this method, using kaolin as diluent, it was found that 1 per cent of montmorillonite gave a visible 17·7 A. reflexion on an aggregate diagram.

(3) *Insensitivity to hydration conditions*. Samples which were (*a*) dried on a steam bath, (*b*) dried over phosphorus pentoxide at room temperature, and (*c*) allowed to stand over water for a week at room temperature gave essentially the same powder diagram. In particular, the position of the 17·7 A. reflexion seemed to remain quite unchanged. Thus the glycerol treatment may be said to eliminate the undesirable results of the expanding lattice of montmorillonite. Other polyhydric alcohols, such as ethylene and trimethylene glycols, give rather similar effects with montmorillonite; but in all other cases tried so far, the basal spacing varies with the state of hydration.

(4) *Easy distinction from other clay minerals, including illite (hydrous mica)*. The 17·7 A. reflexion is very characteristic, and the second-order reflexion at 8·85 A. does not interfere with a line given by any other likely mineral. Moreover, tests with illite (from Grundy County, Illinois) show that the position of its basal reflexion is completely unaffected by the treatment. In view of the claims of Jackson *et al.*[3] that an expansion of the illite lattice may be caused by certain hydration procedures, this point is not without importance.

Part of the work mentioned above was done during the tenure of a grant from the Agricultural Research Council, to which I wish to express my thanks.

## A Modification of the Method for Estimating the Anti-bacterial Activity of Fungi that are Difficult to Grow on Liquid Media

RECENTLY[1] we published a method which was specially designed to estimate the anti-bacterial activity of certain fungi, for example, the Basidiomycetes, which are difficult to grow on liquid media. Briefly, the method consisted in cutting a disk from a growing fungus colony and dropping it into a plate of warm agar which had been bulk-seeded with bacteria. In case of a positive result a zone of bacterial inhibition was produced round the disk. The method stated that "all disks are cut at approximately the same distance from the edge of the colony". An attempt to determine what distance from the edge of the colony would give the best result brought out certain objections to the method and led to the present modification.

The main difficulty was that the disks did not always produce a zone of inhibition of uniform width; in some cases the width on one side of the disk was twice that on the other side. Assuming the colony was allowed to grow to a diameter of 2½ in., the radius permitted disks of 11 mm. to be cut at different distances from the edge, and it was found that there was variation in the shape of the zone according to whether the disk was cut from near the edge or near the centre of the colony. The zone might be perfectly centric around the disk wherever the disk was cut out; but in most cases it was not. In general, there were two variants on the centric type. Fig. 1 *A* shows a disk (*d*) cut near the edge (*e*) and some distance from the centre (*c*) of the fungus colony.

When the disk was placed in the bacteria-seeded plate, the zone of inhibition might be of the type shown in Fig. 1 *B*, that is, having the widest part of the zone of inhibition at that part of the disk which had been towards the centre of the fungus colony, or it might be of type Fig. 1 *C*, where the widest part of the zone was at that side of the disk which had been farthest from the centre of the colony. The first

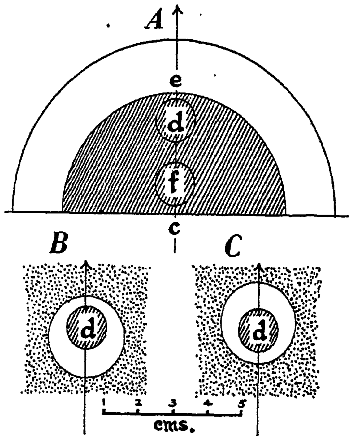

FIG. 1. FUNGUS MYCELIUM SHADED ; BACTERIAL COLONIES STIPPLED. EXPLANATION IN TEXT.

type indicated that it was the older region of the mycelium that was producing the greatest concentration of inhibitory substance, the second type indicated that it was the young mycelium near the growing edge that was responsible for the higher concentration. Apart from the interesting fact that in some fungi it is the older and in others the younger part of the mycelium that produces inhibitory substances, apart also from the difficulty of using the method as any more than a positive/negative test, the above variations might be so pronounced as completely to invalidate the results. When two disks were cut from certain fungus colonies, one (*d*) near the edge and the other (*f*) near the centre, the one gave a zone of inhibition, centric or eccentric, but the other gave no zone at all. Hence the position from which the mycelial disk was cut was of paramount importance. To obviate the necessity for cutting more than one disk, the following modification of the method was adopted, and has proved to be quite as simple and more informative than the original.

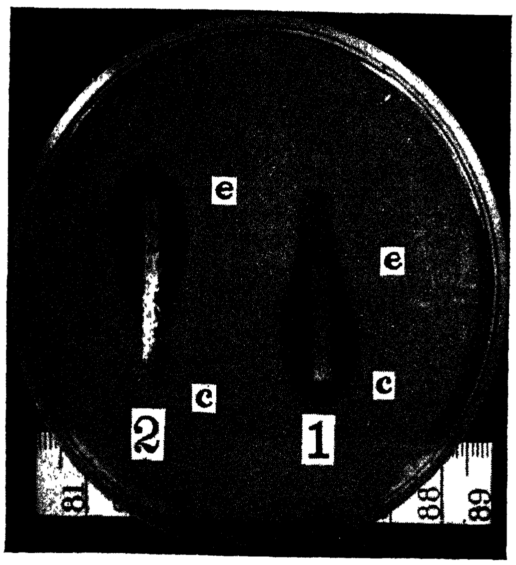

FIG. 2. SHOWING BOTH TYPES OF INHIBITION.

A strip of mycelium and agar 4 mm. wide is cut, by means of a safety razor blade apparatus, right across the centre of the plate containing the fungus colony. This strip is divided at the centre into two equivalent halves, one half is put into a plate of warm agar bulk-seeded with *Staphylococcus aureus* and the other half is put into a similar plate seeded with *Bacterium coli*. Comparable results against the two types of bacteria are thus possible, and comparisons between the effects produced by different fungi and between the effects produced by the same fungus on different media are also facilitated. The sort of result which is obtained is shown in Fig. 2, which is a photograph of two mycelial strips in a plate of *Staph. aureus*.

Strip No. 1 is cut from a growing colony of the basidiomycete fungus *Tricholoma nudum*, a fungus which typically produces the greatest concentration of inhibitory substances from the older region of the mycelium. Strip No. 2 is cut from another basidiomycete, *Clitocybe aurantiaca*, which produces inhibitory substances only from the younger region of the mycelium. The degree of inhibition is determined by measuring the greatest diameter of the zone of inhibition wherever that may be in relation to the mycelial strip. So far as we yet know, growing any given fungus on different media may alter the degree but does not alter the type of inhibition.

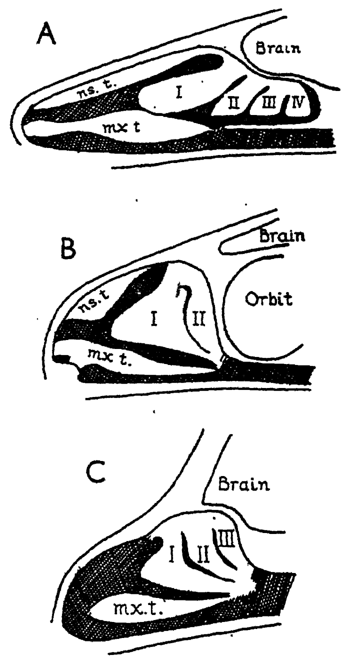
## Meristic Variation and Reversibility of Evolution

PROJECTING into the nasal fossa of any generalized metatherian or eutherian mammal is a series of turbinals, namely, a naso-turbinal (Fig. *A*, *ns.t.*), a maxillo-turbinal (*mx.t.*) and four ethmo-turbinals (I–IV), and there can be little doubt that such an arrangement characterized the remote ancestors of the Primates. But in all primitive Primates (from which we exclude the Lemures), including such forms as *Tarsius* (Fig. *B*), *Hapale*, *Chrysothrix* (*Saimiri*), *Cebus* and *Lagothrix*, there are but two ethmo-turbinals (I, II), for in these forms the orbital cavities have so enlarged as to obliterate by their approximation the posterior part of the ancestral nasal fossa. In the baboon, gibbon (Fig. *C*), chimpanzee and gorilla, and in man, the nasal fossæ are again enlarged, partly at least as a result of the growth in width of the skull-base in support of an enlarged brain, and in all these forms three[1], and in man sometimes four[2] or even five[3], ethmo-turbinals may be developed. The phylogenetic trend in Primates seems, therefore, to have been towards a reduction of the turbinal series in early forms and a secondary expansion thereof in certain of their descendants.

Dollo's 'law of irreversibility', even in its modern phrasing: "Evolution is reversible in that structures or functions once gained may be lost, but irreversible in that structures or functions once lost can never be regained"[4]—does not apply here, for ethmo-turbinal III has been lost in primitive Primates and has



reappeared in certain recent forms. Arber[5], quite independently of Dollo, formulated from botanical evidence a 'law of loss', the "general rule that a structure or organ once lost in the course of phylogeny can never be regained; if the organism subsequently has occasion to replace it, it cannot be reproduced, but must be constructed afresh in some different mode", and later collected such data as had been submitted from time to time as evidence contrary to Dollo's law. Such evidence included the re-acquisition of a lost toe in a laboratory race of cavy, the re-development of lateral digits in some horses, the occasional presence of a fifth stamen in anomalous Iris specimens. Arber pointed out that these were all cases of meristic variation and that Dollo's law did not apply to them.

The present instance of the nasal turbinals is also meristic in nature, but is derived from normal anatomy and not from teratology: it is bound up with the fundamentals of Primate evolution.

The ambiguity of Dollo's law depends upon the interpretation of the words 'structure' or 'organ'. Presumably if the entire Primate ethmo-turbinal series had been phylogenetically lost, no single turbinal could ever have been regained: but so long as even one member of the series persisted in primitive Primate forms, the redevelopment in descendant recent forms of the full turbinal complement remained a possibility. It seems advisable, therefore, to add to the law a rider to the effect that, in the case of structures constituting a series, the law applies to the series as a whole, and not to the individual members thereof.

## Failure of *Iso*-Immunization to *M* and *N* Agglutinogens in Man

Since the *A*, *B* and *Rh* agglutinogens so frequently invoke an immune response, either between mother and baby or as the result of incompatible blood transfusions, speculation has arisen to explain why differences in *M* and *N* type of donor and recipient, or of baby and mother, do not have the same effect.

The *M* and *N* agglutinogens are good antigens in animals; but the work of Kosjakov and Tribulev[1] may provide an explanation for the absence of any regular response to the *M* and *N* antigens in man. In an attempt to demonstrate the presence of these substances in the body tissues by means of the inhibition of the corresponding anti-serum, Kosjakov and Tribulev found that non-specific inhibition was so marked that the result was always such as to suggest that both *M* and *N* were present in the tissue under investigation. They discovered, however, that if, for example, the tissue thought to contain the *M*-group substance was first saturated with an anti-*N* serum it was then capable of specifically inhibiting an anti-*M* serum. Similarly, before specific absorption by *N*-group substance could be demonstrated it had first to be saturated with anti-*M* agglutinins.

This suggests that anti-*M* or anti-*N* agglutinins will only rarely appear in the serum of a mother who is carrying a baby of dissimilar *M* or *N* type, or following a blood transfusion, because of the marked non-specific absorptive capacity of human tissues for these *iso*-agglutinins.

## Lichen Substances Containing Nitrogen

It is a matter of interest that, notwithstanding the very large number of substances that have been isolated from lichens, there is only one recorded example of a material containing nitrogen, namely, picroroccellin, isolated by Stenhouse and Groves in 1877 from a variety of *Roccella fuciformis*, and to which they attribute the formula $C_{27}H_{29}O_6N_3$.

From the lichen *Lecanora epanora* we have isolated two yellow nitrogen-containing constituents, rhizocarpic acid and epanorin. Rhizocarpic acid, which is found in many lichens, has hitherto been regarded as consisting solely of carbon, hydrogen and oxygen; we find that it has the formula $C_{28}H_{23}O_6N$ and that, on hydrolysis with strong alkali, it breaks down into methyl alcohol, oxalic acid, phenyl acetic acid and a colourless acid of formula $C_{17}H_{17}O_3N$. Our analytical data for epanorin which, like rhizocarpic acid, contains one methoxyl group, accord best with the formula $C_{21}H_{21}O_5N$; on alkaline hydrolysis it gives rise to methyl alcohol, oxalic acid, phenyl acetic acid and a colourless acid of formula $C_{14}H_{19}O_3N$. The products of hydrolysis indicate $C_{25}H_{25}O_6N$ as an alternative formula for epanorin.

## Alleged Role of Fructofuranose in the Synthesis of Levan

THE view was long widely entertained that cells synthesize macromolecules of polysaccharides and proteins by a reversion of the process of hydrolysis. It has been suggested accordingly that the synthesis of the polyfructoside levan specifically from aldosido< >fructofuranosides (sucrose, raffinose) involves two distinct steps: first, hydrolysis of the substrate; secondly, polymerization of fructofuranose by a condensation involving removal of water[1]. Bacteria which form levan from sucrose do so also from raffinose[2]. This polymerative type of sucrose degradation is concurrent with an ordinary hydrolytic inversion[3,4]. The same bacteria ferment levan[3]. Investigators might be tempted by these correlations to consider the enzyme system, levansucrase, to be but a mixture of invertase and polyfructosidase. It is shown below, however, that this view cannot be valid.

(*a*) Owen[5] added yeast invertase solution to cultures of bacteria growing in a sucrose medium. The addition did not augment but inhibited formation of levan by the cells. The findings suggested that invertase is not an essential component of the levan-forming enzyme, but since it referred to living and proliferating cells a final conclusion in this respect could not be drawn[6]. The recent preparation of cell-free levansucrase from *Aerobacter*[3] has made it possible to carry out Owen's experiment in conditions free from the criticisms to which his earlier attempt is open. It has been found that addition to this levansucrase of yeast invertase in amount sufficient to double the rate of sucrose decomposition does not affect levan production in solutions containing a high initial concentration of sucrose (more than 5 per cent). In solutions containing levan-formation-limiting concentrations of sucrose (less than 2 per cent), addition of yeast invertase to the levansucrase caused inhibition, rather than augmentation, of levan production.

On the view that fructofuranose is the substrate actually polymerized by levansucrase, it is still possible to explain the failure of invertase to accelerate levan production from a non-limiting concentration of sucrose by assuming that in this process hydrolysis, though essential, is not a rate-limiting step. This complicating possibility is eliminated where the rate of levan production is known to be dependent on the sucrose concentration. It is similarly eliminated in reactions carried out on raffinose. Levan is produced much more slowly from raffinose than from an equivalent concentration of sucrose[7]. If the reaction proceeds via fructofuranose, the rate-limiting step on raffinose can only be hydrolysis, subsequent steps by the terms of the theory being identical for both sucrose and raffinose. Yet addition to levansucrase of enough yeast invertase to render the rate of raffinose hydrolysis by the enzyme mixture equal to the rate of conversion of sucrose by levansucrase alone failed to augment, and in the long run inhibited, the rate of production of levan from raffinose. The conclusion is therefore confirmed that invertase is irrelevant to levan production from sucrose and raffinose by levansucrase.

(*b*) There is further direct evidence that fructofuranose is not a substrate which can be polymerized by levansucrase. Isbell and Pigman[8] have concluded on the basis of measurements of optical rotation that fructose in aqueous solution is an equilibrium mixture of fructofuranoses and fructopyranoses. The recent demonstration that glucose-1-phosphate (Cori ester) and fructose form a dynamic equilibrium with sucrose and phosphoric acid in the presence of a specific enzyme[9] corroborates this view. Addition of fructose to sucrose does not inhibit levan production from the latter, yet fructose itself, although it presumably contains ready fructofuranose, is not converted into levan by levansucrase[7]. Similarly, levansucrase fails to form levan from reaction mixtures in which fructofuranose is sustainedly liberated in *statu nascendi*, for example, in reaction mixtures of methyl gamma fructoside + yeast invertase, and of inulin inulase.

(*c*) Extracts of an *Aerobacter*, although they produce levan from sucrose and hydrolyse the latter as well, do not hydrolyse levan. Thus they contain levansucrase and invertase but no polyfructosidase (levanase)[7]. On the other hand, takadiastase and an extract of a *Torula* yeast have been found to hydrolyse levan and inulin as well as sucrose, yet produced no levan from the latter. Thus they contain invertase as well as polyfructosidase yet are without levansucrase.

The conclusion is therefore indicated that fructofuranose is not an intermediary of levan synthesis from aldosido< >-fructofuranosides. The view of macromolecular biosynthesis as a reversion of hydrolase action apparently fails to describe levan production, even as it fails to depict the biological production of glycogen and starch.

## A Blind Woodlouse

WHEN examining some specimens of *Armadillidium vulgare* (Latr.), kindly sent to me by Dr. H. W. Howard of Cambridge from the University Farm, I noticed that a female specimen of the variety "Black type B" of Howard[1] was entirely void of eyes or any trace of them. In this example there is no trace of any visual elements or even pigment. The chitin on the cephalon, where the eyes should be, is very slightly convex, shelving down laterally and inwardly.

During the past thirty years, I have examined many thousands of specimens referable to this species, but I have never met with one in which the eyes were absent, or in any other species of terrestrial isopod excepting in truly cavernicolous ones.

# NATIONAL FLOUR AND BREAD

From the Scientific Adviser's Division, Ministry of Food

THIS report, the fifth to be issued[1], covers the samples of flour examined in the period January 1 to September 2, 1944, and loaves from January 1 to October 2.

## Quality of Flour

423 samples were analysed with the following results:

| Fibre | | Vitamin $B_1$ | |
|---|---|---|---|
| Value per cent | Per cent of samples | I.U./gram | Per cent of samples |
| 0·4 or less | 10·9 | 1·1 or more | 3·3 |
| 0·5 ,, | 52·7 | 1·05 ,, | 12·3 |
| 0·55 ,, | 70·7 | 1·0 ,, | 35·7 |
| 0·6 ,, | 80·7 | 0·95 ,, | 62·1 |
| 0·7 ,, | 92·7 | 0·9 ,, | 82·0 |
| 0·8 ,, | 98·1 | 0·8 ,, | 97·1 |

The fibre figures are corrected for any added white flour.

*Riboflavin, Nicotinic Acid, Iron, Protein, Ash and Maltose.* For these determinations the samples received in each of the months January–June inclusive were compounded.

| Month | No. of samples | Riboflavin (μgm./gm.) | Nicotinic acid (μgm./gm.) | Iron (mgm./100 gm.) | Protein per cent | Ash* (per cent) | Fibre (per cent) | Maltose (per cent) |
|---|---|---|---|---|---|---|---|---|
| January | 72 | 1·2 | 17 | 2·15 | 10·9 | 1·0 | 0·50 | 2·35 |
| February | 64 | 1·2 | 17 | 2·12 | 10·8 | 0·97 | 0·50 | 2·3 |
| March | 60 | 1·3 | 17 | 1·94 | 10·0 | 0·96 | 0·50 | 2·3 |
| April | 60 | 1·4 | 17 | 1·98 | 10·8 | 0·94 | 0·50 | 2·1 |
| May | 40 | 1·4 | 16 | 2·01 | 10·9 | 0·96 | 0·50 | 2·05 |
| June | 50 | 1·3 | 17 | 2·20 | 10·8 | 1·04 | 0·50 | 2·3 |

* All the flours were fortified with calcium carbonate at the rate of 7 oz. per sack of 280 lb. The ash due to this addition would average 0·12 per cent. No skim milk powder was added after March 1944.

Average figures for National flour in the period were therefore:

| | | | |
|---|---|---|---|
| $B_1$ | 0·95–1·0 I.U./gm. | Protein | 10·7 per cent |
| Riboflavin | 1·3 μgm./gm. | Fibre | 0·50 ,, |
| Nicotinic acid | 17 ,, | Ash | 0·98 ,, |
| Iron | 2·07 mgm./100 gm. | Maltose | 2·2 ,, |

*Granularity.* In 1944 (up to October 4) 549 samples of flour have been examined with the following results:

| Samples | % over 5 silk | % over 8 silk |
|---|---|---|
| 1–100 | 1·2 | 4·7 |
| 101–200 | 1·1 | 4·4 |
| 201–300 | 0·8 | 4·1 |
| 301–400 | 0·7 | 3·7 |
| 401–549 | 1·0 | 4·3 |

Aperture No. 5 silk = 0·270 mm.
,, No. 8 ,, = 0·190 ,,

*Baking Quality.* All the flours were test-baked under optimum conditions of water absorption and fermentation, and the resulting bread graded according to quality (commercial standards).

257 samples of flour gave good bread = 60·7 per cent of samples.
81 ,, ,, ,, ,, fair-good ,, = 19·2 ,, ,, ,, ,,
67 ,, ,, ,, ,, fair ,, = 15·8 ,, ,, ,, ,,
18 ,, ,, ,, ,, poor ,, = 4·2 ,, ,, ,, ,,

## Quality of Bread

3,358 loaves from different parts of Great Britain were graded for quality (commercial standards).

Good = 461 loaves = 13·7 per cent
Fair-Good = 1393 ,, = 41·5 ,, ,,
Fair = 1027 ,, = 30·6 ,, ,,
Poor = 477 ,, = 14·2 ,, ,,

It will be observed that the first two groups totalled 55 per cent against 80 per cent for the flours baked under ideal conditions in the laboratory.

This work was carried out at the Cereals Research Station, Ministry of Food, St. Albans.

# PHYSICO-CHEMICAL ANALYSIS IN U.S.S.R.

IN 1904 Prof. N. S. Kurnakov (1860–1941) invented a new form of recording pyrometer which was a great improvement on that of Roberts-Austen. In 1910 Prof. A. A. Baikov still further improved this pyrometer by a modification which allowed the recording of the differential curve to be superimposed on the ordinary cooling or heating curve. This apparatus provided a very delicate method for the thermal analysis of alloys and minerals, called by Kurnakov in 1913 'physico-chemical analysis'[1]. Through the initiative and enthusiasm of Kurnakov, a very flourishing school of research was established, and in 1918 a special Institute of Physico-Chemical Analysis was founded at the Academy of Sciences.

The scope and purpose of this Institute was defined by Kurnakov in the following words: "The Institute of Physico-Chemical Analysis has for its aim the study of the relations between the composition and the measurable properties of systems in equilibrium of two or more components. Being in reality one of the subdivisions of general chemistry, physico-chemical analysis can be of a wide application in the border regions of theoretical and applied science—mineralogy, petrology, geology, metallurgy and applied and structural mechanics. It is a very significant fact that a systematic investigation of the diagram 'composition-properties', the essential method of this new chemical discipline, allows us to draw conclusions about the nature of solid, liquid or gaseous substances, without subjecting them to the usual chemical operations of separation. Because of that, a whole range of substances—alloys, glasses, slags, rocks, liquid and solid solutions, colloidal systems and various ores—are now included within the range of a systematic chemical investigation"[2].

In 1940 the friends of N. S. Kurnakov decided to celebrate his eightieth anniversary by publishing a special volume of collected papers. The sad event of Kurnakov's death on March 19, 1941[3], made it necessary to recast the proposed volume and a memorial volume was published instead[4]. This volume contains twenty-nine articles written by Kurnakov's close associates and friends. The first eight articles deal with the biography, bibliography and the scientific work of Kurnakov. Every application of the physico-chemical analysis—alloys, organic

and complex compounds, minerals and ores—is discussed in a special article by a leading authority on this subject. The remaining articles deal with original research and they include the following topics: thermographic methods, viscosity of liquid systems, properties of various chemical systems and alloys, potash salts, etc. The volume is well printed and provided with the portrait of N. S. Kurnakov and numerous plates of photomicrographs and diagrams. Unfortunately there are no English summaries.

It is rather difficult to give an adequate account of the achievements of Kurnakov's school of research, but specialists in given branches of chemistry and other sciences are probably acquainted with the abstracts of Russian papers and with the papers published in the *Z. anorg. Chem.* and *J. Inst. Metals.* The whole range of these publications can be roughly assigned to three sections: (1) metals, (2) minerals and ores, and (3) general chemistry. The works dealing with metals are chiefly concerned with the thermal study of alloys from the point of view of the phase rule, and a very detailed correlation of the composition with viscosity, hardness, electro-conductivity, etc., is usually made. The works dealing with minerals and ores cover a wider ground. First in order of importance comes the study of the equilibrium of salt solutions, a study which not only made a valuable contribution to theoretical science but also greatly helped in the development of Russian salt deposits and the salt industry. The application of physico-chemical analysis to other minerals and ores has embraced practically all classes of minerals: silicates, carbonates, oxides, borates, native elements, etc. Probably the most outstanding achievement was the study of the minerals of the platinum group, clay minerals and bauxitic minerals, a work which had a most important practical application in the U.S.S.R. Of the problems concerned with the general chemistry one may mention the study of organic compounds, compounds with complex radicals, the general study of equilibrium systems and the topology of the equilibrium diagram.

# SOLAR RADIATION OBSERVATIONS AND VOLCANIC DUST

It was observed by Dr. C. G. Abbot that dust from the Alaskan volcano Katmai in June 1912 affected the transparency of the atmosphere in the northern hemisphere, but failed to influence the pyrheliometric observations at Arequipa, Peru. This led George G. Gallagher of Glendale, California, to inquire whether or not dust from southern hemisphere volcanoes influenced the atmosphere in the northern hemisphere. This matter has just been investigated by L. B. Aldrich from the records of the Smithsonian solar-radiation stations for the Chilean Andes eruptions of April 1932*.

* "Smithsonian Pyrheliometry and the Andean Volcanic Eruptions of April 1932", by L. B. Aldrich. *Smithsonian Misc. Coll.*, **104**, No. 6, July 3, 1944.

The Andean eruptions of 1932 started on April 10, involving some seven volcanoes extending two hundred miles along the Chile–Argentine border from Tupungato (altitude 2 ,000 ft., lat. 33·5° S.) southward to Quizapu (altitude about 10,000 ft.). Loud explosions were heard 100 miles on either side of the volcanoes. The explosions continued for three days. Surrounding towns were in semi-darkness owing to the steady fall of dust and ashes. In Montevideo, 850 miles away, the steady fall of dust continued for many hours. The late Dr. C. Davison estimated the fall of dust over the area to be more than five cubic miles. Capt. R. Wooten, United States Air Attaché at Santiago, who flew across Quizapu at an altitude of 14,000 ft., estimated that at the time of greatest activity the smoke column rose to a height of 30,000 ft. Evidences of unusual dust in the atmosphere were noted at Wellington, New Zealand, on May 7, reaching a maximum about May 26. Unusual skies were also reported during May from various places in South Africa.

During this time the Smithsonian Institution was operating solar-radiation stations at Montezuma (latitude 22° 40′ S., longitude 68° 56′ W.) and at Table Mountain, California (latitude 34° 22′ N., longitude 117° 41′ W.). At both these stations, on all days when the sky around the sun was clear, observations were made with the silver-disk pyrheliometer, measuring the total solar radiation received upon a surface normal to the radiation. Simultaneously, readings were taken with a pyranometer, measuring the brightness of the sky in a circular zone about 10° wide, concentric with the sun. These pyranometer readings are an index of the quantity of dust in the atmosphere. Values of pyrheliometry and pyranometry at air mass 2·0 (solar altitude 30°) were selected from the observations and used uncorrected to mean solar distance. These were grouped by months and so chosen that the average amount of water vapour in the air above the station was the same in each year for a given month. The amount of water vapour in the air may be represented by the spectrobolometrically determined precipitable water value. The year 1930 was taken as a standard for comparison. The following tables, obtained by L. B. Aldrich, indicate the results of the investigation.

PERCENTAGE DEVIATIONS OF PYRHELIOMETRY AND SOLAR CONSTANTS FROM CORRESPONDING MONTH OF 1930.

| | Pyrheliometry | | |
|---|---|---|---|
| | Montezuma | Table Mountain | Solar Constant |
| Month | per cent | per cent | per cent |
| May 1932 | −3·7 | +0·8 | −0·4 |
| June ,, | −3·4 | −0·5 | −0·1 |
| July ,, | −2·6 | −0·1 | −0·1 |
| Nov. ,, | −2·1 | 0·0 | −0·2 |
| May 1933 | −0·1 | −0·4 | −0·4 |

PERCENTAGE CHANGE OF SKY BRIGHTNESS AROUND THE SUN FROM CORRESPONDING MONTH OF THE YEAR 1930.

| Month | Montezuma | Table Mountain |
|---|---|---|
| | per cent | per cent |
| May 1932 | +157 | −23 |
| June ,, | +114 | − 3 |
| July ,, | + 87 | − 5 |
| Nov. ,, | + 44 | + 1 |
| May 1933 | − 19 | + 8 |

No effect of the Andean eruptions is discovered in the Table Mountain, California observations. A definite effect occurs in the Montezuma pyrheliometer values, with a maximum of 3·7 per cent depletion in May 1932, and an average of 3·0 per cent for the months May, June, July, November. This agrees with Mr. Gallagher's estimate.

From the Montezuma records, the following unusual sky observation reports are taken (1932: C. P. Butler, director).

April 13. Horizon to south very hazy with yellowish-looking dust. Nothing further is noted until—

April 22. Good sky. Very hazy over mountains to east.

April 23. Very heavy layer of yellowish haze over mountains to east, extending up to about 10°.

April 24. Very poor sky. Streaks from horizon to zenith, with whitish glare about sun.

April 25 and 26. Same notes as on April 24.

April 27 through 30. Dust in atmosphere almost totally obscures sun.

On April 30 the pyranometer value at air mass 2·0 was 0·131 calorie—ten times the normal value.

It should be noted that Montezuma is more than eight hundred miles north of the erupting volcanoes.

## CARE OF THE WOUNDED

THOSE who had the experience of being transported, after the War of 1914–18, from, say, the less civilized Iraq of those days to a bed in one of the temporary military hospitals in England considered that they were being handled by an organization which it would be difficult to improve. But we realize, when we read the three articles contributed by a Special Correspondent to the *Lancet* (253, August 19, 1944; 278, August 26, 1944; 383, September 16, 1944), how much more is now being done for the wounded and the sick. These three articles on the wounded from Normandy must be read; they cannot be summarized. They explain why the casualty-rate among the wounded has been low. The doctor and the medical organization go right forward into the battle; paratroops and tanks have their field ambulances; the soldier knows much more about first-aid and about how to keep himself fit; surgical treatment is given early; blood transfusions are given much earlier; penicillin is available everywhere; and air transport, described in the second article, has been well organized. When they get to Britain, the wounded pass into the hands of the home hospital services and their network of ancillary organizations, which extend right back to the humblest civilian who goes along, when he is asked to do so, to give a pint of blood. The destinies of that blood have been described in the Press and pictured on the cinema screen. They are symbolic of the whole service. It is to be hoped that, after the War, this organization will be applied to national life in peace as well as in war, and that the soldier will bring back into civil life the knowledge of how to keep fighting fit which the R.A.M.C. has taught him so well that "nothing like it has ever been done either in military or civil life".

For those who are interested in this subject, the article entitled "Military Surgery in Geographical Perspective", by Ian Aird, late Lieut.-Colonel R.A.M.C. (*Edinburgh Med. J.*, 51, 166; April 1944) will be of great interest. The author deals with surgical strategy and tactics in Libya and discusses the influence of the physiography, climate, water supply, soil bacteriology, dust and sand storms, populations and communications of Libya on the planning of surgery for the campaign there. Little help was obtained from the history of previous North African campaigns. The rapid movement of the war there demanded mobile, self-contained units, and the caravan- and tent-operating theatres used are shown in photographs. The rest of the article describes the surgical technique employed, the water shortage and evacuation of the wounded by air. It may be compared with many other articles on the treatment of war wounds which have appeared in the medical Press.

Almost as frequent have been articles on the transport of the wounded or of those injured in air raids. Among these there have been numerous descriptions of stretchers designed for rapid transport of injured people and adapted for use for artificial respiration as well. D. G. Duff (*Lancet*, 798, June 17, 1944; see also the *Lancet*, 739, June 3, 1944) describes one of these stretchers. Dr. Duff's stretcher is the result of experiments made over six years, experience of climbing accidents being included. Photographs of it illustrate its use. It is comparable in weight and ease of production to the standard army stretcher, and can be used as a breech buoy and for Eve's rocking method of artificial respiration. Runners beneath it enable it to "be its own vehicle" on any slope and on rock, grass, scree, heather, ice and snow; or it can be used for lowering a patient from a window. A wheeled undercarriage is available and a collapsible form of it can be got into a package 4 ft. 6 in. × 10 in. × 4 in.

## BIOLOGICAL STUDIES IN BRAZIL

BRAZILIAN biologists and medical men have made, and are making, valuable contributions to knowledge. The wide field which they cover is indicated, not only by their medical journals, but also by the policy of some of their biological periodicals, which publish articles on subjects which, in other countries, would be printed in medical literature. Thus the *Revista Brazileira de Biologia* (3, No. 4; 1943) contains papers on immunology, such as those on protection tests with Felix's antityphoid serum, on oxidation and reduction of complement and on the antibodies to the virus of equine encephalomyelitis; and others on cryo-epilepsy, on Henry's melano-flocculation reaction and on Wolff's buffer-precipitation test in malaria, Chagas's disease and schistosomiasis. Another paper discusses the action of acetylcholine and of adrenalin on the coronary arteries of the Brazilian macacus monkey, *Allouata fuscus*. The rest of this issue deals with more specifically biological subjects. Thus there are articles on two Lepidoptera, *Automolis* and *Rhipha*; and on the unity or duality of the males of the hymenopterous parasite, *Telenomus fariai*, in which the author concludes that the two classes of males are morphologically identical, produce the same progeny from the female and always have ten chromosomes, while the female has twenty. Their difference in size depends on the amount of food that is available. Other articles deal with a new trematode species, *Catadiscus mirandai*, from the large intestine of *Hemipipa carvalhoi*, with some spiders of Chile, with two new species of *Stenolemus* (Reduviidæ, Hemiptera) and with the hyoid and laryngeal apparatus of some Microchiroptera. Botanists will be interested in the article on the nomenclature of *Capsicodendron Dinisii* (syn. *C. pimentiera*, Canellaceæ). The social importance of scientific investigation is discussed by Dr. Oswaldo Cruz, of the famous Institute which bears his name.

Another Brazilian biological journal, *Zoologia* (No. 7. 1943. Boletim 32, Universidade de São Paulo, Brasil), although chiefly biological, contains a paper by Paulo Sawaya on the occurrence of acetylcholine in the cardiac tissues of the marine crab, *Callinectes danæ*, which "is perhaps the commonest swimming crab in Brazil". A large quantity of acetylcholine was found in the cardiac tissue. The technique of attempts to perfuse the heart is described and the effects on the heart of acetylcholine, eserine, atropine, nicotine and adrenalin are described. Extracts of the cardiac tissue of *Callinectes danæ* contained substances which acted like acetylcholine on the hearts of the amphibians *Bufo marinus* and *Siphonops annulatus*. The experiments indicated that *Siphonops annulatus* can be used for testing the action of acetylcholine. Five plates record the kymograph tracings (cardiograms) obtained with the hearts of these three species.

The greater part of this issue is, however, occupied by a paper of 246 pages on the Naididæ of Brazil, by Ernesto Marcus, with a summary in English of ten pages, a bibliography of seven pages and 33 plates. The paper discusses the structure, bionomics and taxonomy of 24 species, all found near the city of São Paulo and in the State of São Paulo. They belong to the genera, *Chætogaster*, *Nais*, *Dero*, *Aulophorus*, *Pristina* and *Naidium*. Some problems of variability, morphogenesis, regeneration and histology are considered.

In the same volume, Michel P. Sawaya discusses the intrazoœcial rings of the Crisiid Bryozoa, and Domingos Valente describes his work on the effect of numbers of individuals on the oxygen consumption of the crab *Trichodactylus petropolitanus*, which normally lives in darkness under stones and water plants in rivers. The author concludes that the isolated animal uses oxygen at a greater rate than do groups of four crabs; and two crabs used more than four. This group effect is not eliminated by darkness. The effect of visual stimuli on oxygen consumption was studied in crabs placed in relation to their own mirror images in aquaria mirrored on one vertical side. The oxygen consumption of isolated crabs thus placed in contact with their own mirror images was decreased. Mirror image and group effects are thus both positive, but the former were not very marked.

G. LAPAGE.

## SYSTEMATICS OF THE POTATO

A THOROUGH understanding of potato taxonomy is a necessary pre-requisite of a large-scale programme of breeding for new types. With this in view the British Empire Potato Collecting Expedition sent out by the Imperial Agricultural Bureaux during 1938–39 made extensive collections in Mexico and South America. The systematic results are now described by Dr. J. G. Hawkes (Imperial Bureau of Plant Breeding and Genetics, Cambridge, pp. 142, June 1944, 7*s.* 6*d.*), who has classified all the material obtained on a basis of morphological, geographical and cytological criteria. Five new cultivated and thirty-one new wild species are described in addition to very many new varieties and forms; but although some twenty cultivated and one hundred and fifty wild species of potato are now known, it is concluded that, at least so far as the wild species are concerned, the wealth of variation still lies practically untouched, and probably three or four times as many wild species await discovery in the less accessible regions.

The cytological investigation of the collections shows that it is only in Mexico that the whole polyploid series occurs. Here only six diploid species are known, whereas tetraploid, pentaploid and hexaploid types are common. In South America diploid wild species are the rule, and there are no pentaploid or hexaploid wild species and only one pentaploid cultivated species. Among cultivated species in every country tetraploid clones occur much more frequently than diploids, triploids and pentaploids.

As regards the origin and evolution of cultivated potatoes, reasons are advanced for supposing that moderately high-yielding wild potatoes were first taken into cultivation in the Lake Titicaca – Cuzco region of north Bolivia and south Peru. Light is thrown upon the problem as to which types of potato were first cultivated by an analysis of the different kinds of weed and semi-cultivated species. This leads to the conclusion that the tetraploid weed species may be either types that had once been cultivated and have now been replaced by higher-yielding varieties of *S. andigenum*, or amphidiploids which were never cultivated to any great extent. The diploid species, on the other hand, are probably the wild species most closely related to our cultivated diploids from which the tetraploids arose before or after their being taken into cultivation. The two tetraploids *S. andigenum* and *S. tuberosum* (*s.str.*) are considered to have had a common origin in the south Peru – north Bolivia region and not to have been derived from distinct wild species, while the evidence as to the origin of the European potato is thought to favour an introduction from the Andes, and most probably Columbia, rather than Chile as has been supposed.

## STRUCTURE OF THE WALLS OF PHLOEM FIBRES

R. D. PRESTON (*Chronica Botanica*, 7, 414; 1943) points out that there is now considerable scope for the botanist, and especially the biophysicist, to make his contribution to the knowledge of the fine structure of the cellulose walls of plant cells.

Owing to their commercial value, the fibres of the phloem (sclerenchyma) have so far been chiefly studied; in these the X-ray diagram indicates the presence of cellulose chains in the longitudinal direction only, while observations on swollen walls by optical methods have led to the view that at least two layers are present and that they differ in direction of the cellulose chains. Crossed cellulose chains definitely occur in the walls of certain algæ. The X-ray diagrams of hemp and jute fibres reveal the presence of only one direction of cellulose chains which runs parallel with the major extinction plane and remains unaltered during thickening processes of the fibre walls.

However, by optical examination of swollen walls, there is indication of heterogeneity in cross-section which does not appear to be accounted for in entirety by the differential distribution of lignin and pectin. The latter causes also differential swelling of the wall in different regions and leads to the production of striations of various kinds; also the swollen material is easily broken into separate fibrils with associated change in direction of cellulose chains, which appears to have misled at least one worker. Swelling under

certain conditions produces a 'ballooning' of the outer layer of the wall in hemp, but not in jute, and this fact, taken in conjunction with associated optical phenomena, suggest that the outer layer in hemp and the inner in jute differ appreciably from the rest of the wall.

It seems clear that in such walls the aggregates of the cellulose complex must differ in their association with one another in the different layers. Comparisons with long collenchyma cells suggest that the optical heterogeneity may be due to a variation in *angular dispersion* of the cellulose chains from layer to layer; this argument is less convincing for hemp and jute fibres, but not precluded by the X-ray diagram. There is therefore still doubt as to whether any chains exist in the secondary walls of these phloem fibres other than those which run in the longitudinal direction.

# FORTHCOMING EVENTS

### Saturday, November 4

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 10.30 a.m.—Discussion on Civil Aviation. General Critchley: "The Selection and Training of Personnel for Civil Aviation"; Major Thornton: "The Economics of Air Transport"; Mr. Roy Chadwick: "Civil Aircraft Design"; Mr. E. W. Hives: "Civil Aero-Engine Design"; Mr. W. P. Hildred: "Route Facilities (Radio, Aerodromes, Meteorology, etc.)".

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. L. Hawkes: "On Jet Coal in the Chalk of Kent".

### Monday, November 6

Farmers' Club (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Mr. J. L. Davies: "The Policy of Expansion of our Dairy Farming".

Society of Chemical Industry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. A. Batley: "Use of Sensitized Metal in Engineering Design".

Royal Geographical Society (at Kensington Gore, South Kensington, London, S.W.7), at 5 p.m.—Lord Rennell of Rodd: "Italian East Africa in 1941".

### Tuesday, November 7

Royal Institution (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Mrs. Jacquetta Hawkes: "Prehistoric Britain", (i) "The Early Colonizations".

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. F. E. Wentworth-Sheilds: Presidential Address.

Sheffield Metallurgical Association (joint meeting with the Sheffield and District Branch of the Institute of Welding) (at the Royal Victoria Station Hotel, Sheffield), at 6.30 p.m.—Mr. H. F. Tremlett: "Arc Welding Problems—Some Notes on Metallurgical Solutions".

Institution of Electrical Engineers (London Students' Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Mr. C. C. Barnes: "Notes on the Design and Manufacture of Impregnated Paper Insulated Power Cables".

Quekett Microscopical Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibits.

### Wednesday, November 8

Institute of Fuel (North-Western Section) (at the Engineers' Club, Manchester), at 2.30 p.m.—Brains Trust on "The Efficient Utilisation of Industrial Waste and Town's Refuse".

Society of Chemical Industry (Food Group) (joint meeting with the Microbiological and Nutrition Panels) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. B. C. J. G. Knight: "Some Wider Aspects of Nutritional Studies with Micro-Organisms".

Chemical Society (joint meeting with the Manchester University Chemical Society and the Royal Institute of Chemistry) (in the Chemistry Lecture Theatre, The University, Manchester), at 5 p.m.—Prof. I. M. Heilbron, F.R.S.: "Chemistry in relation to National Prosperity".

Institution of Electrical Engineers (Transmission Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. D. B. Irving: "Cable Terminations".

### Thursday, November 9

Royal Institution (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "Old and New Descriptions of the Astronomical Universe", (ii) "Stars".

Physical Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. S. K. Mitra: "The Night Sky".

Institution of Electrical Engineers (Installations Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. F. C. Fuke: "Electrical Accessories for Domestic Purposes—Some Notes on their Design and Installation".

Society of Chemical Industry (Edinburgh and East of Scotland Section) (in the Anatomy Lecture Theatre, The University, Teviot Place, Edinburgh), at 5.30 p.m.—Prof. Sir Alexander Fleming, F.R.S.: "Antiseptics" (Lister Memorial Lecture).

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Mr. A. L. Bacharach: "Properties and Uses of Penicillin in relation to Pharmacy".

### Friday, November 10

Association of Applied Biologists (in the Metallurgical Lecture Theatre of the Imperial College of Science and Technology, South Kensington, London, S.W.7), at 2 p.m.—Discussion on "Nomenclature Problems of the Applied Biologist".

Royal Institution (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Mr. G. M. Young: "Equality".

Chemical Society (Sheffield Section) (joint meeting with the Sheffield University Chemical Society) (in the Chemistry Lecture Theatre, The University, Western Bank, Sheffield), at 5.30 p.m.—Prof. W. Wardlaw: "Co-ordination Compounds".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Pests Control Organizer (temporary) for the County of Montgomeryshire—The Executive Officer, Montgomeryshire War Agricultural Executive Committee, County Offices, Welshpool, Mont. (November 7).

Electrical Engineer and Manager of the Metropolitan Borough of Southwark Electricity Department—The Town Clerk, Southwark Town Hall, Walworth Road, London, S.E.17 (endorsed 'Electrical Engineer and Manager') (November 8).

Lecturer (temporary) in Gardening, Biology and Elementary Science in the Caerleon Training College (men)—The Acting Director of Education, Higher Education Department, County Hall, Newport, Mon. (November 11).

Educational Psychologist—The Director of Education, County Offices, Oxford (November 11).

Speech Therapist—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (November 11).

Lecturer in Production Engineering, in Courses (both part-time Day and Evening) leading to Ordinary and Higher National Certificates—The Principal, Derby Technical College, Normanton Road, Derby (November 15).

Drainage Officers (2), and a Water Supplies Officer—The Executive Officer, Shropshire War Agricultural Executive Committee, County Buildings, Shrewsbury (November 18).

Officer in Charge of the Government's Agricultural Training Scheme for ex-Service men and women in the County of Norfolk—The Secretary, Norfolk War Agricultural Executive Committee, Sprowston, Norwich (November 18).

Examiner in Chemistry for the Higher School Examination for the year 1945—The Secretary to the Matriculation and School Examination Council, University of London, at Richmond College, Richmond, Surrey (November 20).

Assistant Lecturer and Demonstrator in Zoology, preferably with special qualifications in Experimental Zoology—The Registrar, University College, Cathays Park, Cardiff (November 30).

University Chair of Concrete Technology tenable at Imperial College of Science and Technology—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (February 26).

Laboratory Attendant in the Department of Zoology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1.

Laboratory Steward or Laboratory Technician—The Registrar, The University, Bristol 8.

Senior Scientific Assistant in the Department of Economics—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Manager of the Intelligence Department—The Secretary, British Cast Iron Research Association, Alvechurch, Birmingham.

Agricultural Training Officer to organize the scheme for the training in Agriculture and Horticulture of men and women released from War service—The Secretary, Berkshire War Agricultural Executive Committee, 1 Abbot's Walk, Reading.

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

Memoirs of the Cotton Research Station, Trinidad. Series A: Genetics. No. 21: The Inheritance of Lint Colour in Asiatic Cottons. By R. A. Silow. Pp. 39. 2*s*. 6*d*. ## SCIENTIFIC RESEARCH AND PATENTS

IN one of the recent series of articles on "Scientific and Industrial Research" published in these columns, it was stated that "When we have thus provided for the effective organization of research in the universities and under direct Government auspices, there will remain a large field of applied research to be undertaken by private industry". The strategy and tactics of research in each of the three divisions indicated in these words must differ from those of the other two, and the opinion was expressed that while "the funds at the disposal of research are utterly inadequate" and that while there will be required "expenditure ranging up to what might well approach 50 millions", there should be "no direct financial aid to research by private firms". There can be no doubt that Government expenditure on this scale and in this way would be greatly in the public interest and to the social advantage. Nevertheless, the view has been expressed that the extremely large expenditure to which the Government is otherwise committed during the next few years makes it unlikely that it will accept the further responsibility of the suggested £50 millions, without some clear indication of means by which it will be able to cover the expenditure more directly than by some possible consequent benefit to the public interest and social advantage. One way of removing this probable reluctance by the Government would be to stress that industrial development and increased employment result from expenditure on research, to make clear what is at present being achieved in this respect by industry, and to suggest how it can be increased.

The close relationship between industrial development, increased employment, and expenditure on research can be shown by reference to the annual reports of many of the larger industrial companies, and an indication of what is at present being achieved is illustrated by figures recently made public by Imperial Chemical Industries, Ltd. The directors of that company have offered to provide at nine universities of Great Britain eighty fellowships of the average value of £600 per annum to be held by senior workers in certain sciences; the research organization of the Company consists of nearly nine hundred fully qualified chemists, physicists, biologists, engineers, and other scientific men, together with more than a thousand skilled assistants. During 1943, its expenditure on research and development in its own works was approximately £2,200,000; and, in addition, £12,500,000 became due to the British and Overseas Governments under the headings of Excess Profits Tax, National Defence Contribution, and income tax. Similar results on a smaller scale have been recorded by many other companies.

This achievement, so directly beneficial to research in the universities and to Government finance, has been made possible by the industrial use in Great Britain of patented inventions; and it should be remembered that for a patentee to comply with the conditions on which he obtains his patent he must

work his invention in Britain. Patents for the "sole working or making of any manner of new manufacture" were by Section 6 exempted from the statute, passed in the year 1624, for the prohibition of monopolies and, under the present Patents Act, a patent may be held invalid if the invention is not being worked in Great Britain on a commercial scale. In spite of these facts, however, many patented inventions are not being so worked and, in other ways, the monopoly rights are being abused and the public interest detrimentally affected. Any amendment of the patent law which would more effectively compel manufacture in Great Britain of a patented invention, prevent other abuse of the monopoly rights, and increase the incentive to inventors, would develop industry and increase employment, and would incline the Government to give more generous assistance to research.

It would seem that the Government has appreciated this aspect of the matter, because some time ago the President of the Board of Trade appointed a representative Committee, with Mr. Kenneth Swan as chairman,

"To consider and report whether any, and if so what, changes are desirable in the Patents and Designs Acts, and in the practice of the Patent Office and the Courts in relation to matters arising therefrom."

In particular, the Committee is requested to give early consideration to, and to submit an interim report or reports on:

"(a) the initiation, conduct and determination of legal proceedings arising under or out of the Patents and Designs Acts, including the constitution of the appropriate tribunals; and

"(b) the provisions of these Acts for the prevention of the abuse of monopoly rights; and to suggest any amendments of the statutory provisions or of procedure thereunder which in their opinion would facilitate the expeditious settlement and the reduction of the cost of legal proceedings in patent cases and would encourage the use of inventions and the progress of industry and trade."

The Committee is now taking evidence on the two matters on which interim reports are asked for, and this evidence includes memoranda by the Trade Marks, Patents and Designs Federation* and by a Joint Chemical Committee†, consisting of representatives of the more important chemical societies and associations of Britain. These memoranda are drawn up in the form of replies to a questionnaire issued by the Government Committee for the guidance of witnesses and are in substantial agreement on the two matters under consideration.

On the important matter of abuse of monopoly rights, about which there has recently been much discussion in Great Britain and more in the United States, the Federation is of opinion that the complaints made on the score of the operation of cartels in Britain in relation to patents are in general not justified.

* Memorandum on Patent Law Reform. Part I. Prepared by the Trade Marks, Patents and Designs Federation. Ltd., 169 Bank Chambers, 329 High Holborn, London, W.C.1.

† Memorandum on Patent Law Reform. Part I. Prepared by the Joint Chemical Committee on Patents, 166 Piccadilly, London, W.1. 1s.

It is stated that no case is known where patents granted for inventions originating in Great Britain have been operated by a cartel to the detriment of the national interest. It is only in the case of international cartels regulating patent rights originating abroad and owned by German interests that there are recorded instances of operations that are to the detriment of the public interest here. The cases the Federation has in mind are those where there is a written agreement under which the parties agree that manufacture under a patent shall be prevented or restricted in Great Britain in favour of importation. It is recalled that British patents are intended to stimulate British manufactures; and if a patented invention is not being worked in Britain, the patented article being made abroad, for example in Germany, and imported into Great Britain, the whole object of the grant of patents is defeated. Examples are cited by the Federation in support of this view, the most interesting being the shortage of 'Atebrin', urgently required for the treatment of malaria when the sources of supply of quinine fell into enemy hands early in the War. The remedy suggested for this type of abuse of the monopoly rights is to grant licences under a patent to persons who are willing to manufacture in Great Britain and to transfer any subsequent beneficial interest in the patent from the patentee to the Crown.

On the matter of abuses of monopoly rights by the suppression of inventions, so often charged against patentees in the popular Press, the Joint Chemical Committee states that these allegations are usually found on examination to be non-existent or to be due to the abuse of wealth. The remedy lies, in its view, first in the grant of licences in the way just indicated; secondly, in giving the Comptroller of Patents power to refuse, subject to appeal to the Court, to grant a patent for an invention which he is satisfied is lacking in inventive merit or in novelty in view of prior user; and thirdly, in some considerable reduction of the costs in patent actions. Both the Committee and the Federation are of opinion that the attitude of the Courts is too 'legalistic' and not sufficiently 'scientific', and that the reinforcement of the Courts by members with some scientific or technological attainments would be in the public interest. They recommend the appointment of a patents tribunal to include one, two or three High Court judges experienced in patent cases and "one or two lay members selected from a permanent panel of, say, six or eight technologically or scientifically qualified persons" who should not undertake any other employment.

The suggestion for the compulsory licensing of all patents, which has been so fully discussed pro and con during the past two years, is opposed on various grounds. It is pointed out that the reason for granting patents is, as stated in the form of patent, "to encourage all inventions which may be for the public good", the encouragement being the right of sole working of the invention for a limited period. The evidence goes to show that patentees in general value highly this right of sole working, and the opinion is expressed that if, by endorsing patents "licences of

right"; this right of sole working is destroyed, the encouragement of the inventor will to that extent be diminished, the flow of invention will be lessened, and the retention of inventions as secret processes will be increased. As regards the commercial exploitation of inventions, not many manufacturers will be prepared to lay down plant for the commercial exploitation of an invention with the risk that it may be a failure, if competitors are free to obtain a licence should it be a success.

It is clear from the memoranda that the evidence which is being submitted to the Committee appointed by the President of the Board of Trade is such as to strengthen the hope of amendment of the patent law so as more effectively to compel manufacture of a patented invention in Great Britain, and make more readily ascertainable the rights of the public in relation to patentees. By this means industry will be developed, employment increased, and the Government enabled to give more generous assistance to research.

# THE CONTRIBUTION OF SCIENCE TO CIVILIZATION

## Science and the Future

By Prof. A. E. Trueman. (The British Way Series, No. 7.) Pp. 64. (Glasgow: Craig and Wilson, Ltd., 1943.) 1*s*. 3*d*.

## The Impact and Value of Science

By Dr. D. W. Hill. Pp. 88. (London, New York and Melbourne: Hutchinson's Scientific and Technical Publications, n.d.) 7*s*. 6*d*. net.

THERE could be no better tribute to the way in which Prof. A. E. Trueman's "Science and the Future" maintains the standard of the earlier pamphlets in "The British Way" series than the manner in which, without disparaging the British contribution to the advancement of science or encouraging the false idea that there are national brands of science, he justifies the inclusion of a pamphlet under this title in the present series. If the British outlook and way of life are to survive, and to continue to make an effective contribution to the building of the post-war world, due regard must be had to the place of science. It would be difficult to find in short compass an abler popular exposition of just what that contribution might be, and of the difficulties which must be faced in organizing science to secure that maximum contribution without endangering the advance of science itself. Prof. Trueman's exposition of the purposes and needs of the scientific investigator is as valuable to the ordinary citizen as his warning on some of the dangers of planning is to the scientific worker himself. One may fairly regard the whole pamphlet as an important contribution to the debate on the organization of scientific and industrial research from this point of view of exposition, and not merely on the grounds of the brief chapters in which those problems are actually discussed in the pamphlet.

This clear view of the fundamentals gives the main value to Prof. Trueman's pamphlet. His note on the characteristics of the scientific method—careful experiment and accurate observation, verification of the evidence, and the effort to eliminate preconceived ideas and personal feelings in forming a judgment or interpreting results—should help to dispel the idea of mystery with which popular thought sometimes still tends to cloak the man of science. So, too, his insistence on the right of independent inquiry, that science can develop only in an atmosphere of freedom and that the value of the scientific worker to the community lies in his originality, should help the conduct of popular discussion on scientific research —a discussion in which the decisions cannot all be taken by scientific men themselves.

Prof. Trueman's pamphlet should do something to bridge the gap between the scientific man and the ordinary citizen to which he himself directs attention. On this, after noting the cultural value of science, he has a chapter on science in education in which he urges that an outline of science is desirable for the appreciation of the world in which we live. The foundation of the intellectual life of any self-respecting man must be a grasp of the outstanding conclusions of science, and the essential feature of general science teaching is that from it should emerge the general picture of the world as seen by the man of science. Prof. Trueman notes the comparative neglect of science in adult education and by the newspaper Press, and indicates developments in extra-mural classes conducted by the universities and the Workers' Educational Association. In regard to the training of scientific workers themselves, he affirms his belief that an atmosphere of research and the cultivation of the outlook of an investigator are essential features of a university training in science. A combination of teaching and research in one individual, he holds, affords a most effective basis for the training of a man of science. In Prof. Trueman's opinion, a research worker who is not specially gifted as a teacher may be a more effective person to train advanced students than an excellent teacher who finds no pleasure in research.

That proposition may depend on particular conditions, but Prof. Trueman's further view that it is essential that intending teachers should not be cut off from the atmosphere of research but should gain some experience of scientific discovery is likely to command general approval.

Of no less interest to the scientific worker are the sections in which Prof. Trueman deals with the organization of science in Britain and with planning for the future. While he appears to admit that there is a lack of co-ordination in the whole national research programme, Prof. Trueman holds that, so far as the planning of science itself is possible, it can suitably be achieved within the organization already available. In this he is in sharp contrast to Prof. Harold Laski, who in an article, "Research, Intelligence and Administration", in the *Political Quarterly*, argued for major changes. Some of the criticism advanced by Prof. Laski would doubtless be conceded by Prof. Trueman, but the latter's survey is more objective and better balanced, and he has probably succeeded in his attempt to give a reasonable presentation in accord with the views of the majority of scientific men.

In any general plan of research, it is essential to make certain that the whole body of knowledge be kept in growth, and that nothing be neglected because it is not immediately useful. Whatever steps therefore we take to organize the study of particular and urgent problems, we must have the widest possible field for unorganized research workers with

free scope to choose their own problems and to tackle them in their own way. This freedom, coupled with responsibility, is essential whatever the nature of the organization which links the scientific worker with the problems to be solved. Here, no less than in indicating how essential a scientific outlook and a wider scientific education are to the scientific planning of the life of the nation, Prof. Trueman's pamphlet should help to keep discussion on the right lines, and it will be read with interest and profit by scientific workers as well as by the larger body of their fellow citizens to whom it is primarily addressed.

Dr. D. W. Hill covers a wider canvas in his book, though he has much ground in common with Prof. Trueman. He, too, is concerned to interpret the scientific outlook and to emphasize that science is a mental discipline and that its first object is not to control or to exploit but to understand. In a chapter on science and industry, he pleads for a better balance between those who may be classed as technologists and scientific workers and those who understand and can use the tools of company law and finance. Dr. Hill never overstates his case, and his plea that industry needs scientific workers, not so much for their professional knowledge as their ingrained method of thought, is more effective because he sees the limitations of technical skill alone. Sanity of outlook, a balanced judgment, ability to correlate the broadest issues and to see the relevance and implications of widely separated facts, a ranging, imaginative, disciplined mind—these also are wanted, but Dr. Hill never wavers from his conviction that a scientific training can develop such qualities.

This conviction he carries into his discussion of science and politics. Here he is less happy. He recognizes indeed that the full use of the scientific expert involves an educated community: the scientifically trained mind imbued with the idea of freedom of thought, grounded in the system of unbiased judgment, might arrive, after weighing the evidence, at a policy to pursue, but it could appeal only to similar minds for understanding and support. Seeing this, and seeing how easily the absence of such a community may lead to the totalitarian State, he has yet missed the essential element in the democratic system. He sees the affinity between the scientific method and the process of democracy; but much of this chapter is crude and lacks the perspicuity with which Prof. Mannheim and Sir Ernest Barker have discussed this problem in recent years.

No such criticism can be advanced against his discussion of science and war. The issues have rarely been laid bare more discerningly, and this chapter is an admirable reply alike to the loose thinking which saddles science with responsibility that lies on the shoulders of the community as a whole, and as an impetus to the impartial examination and study of the causes of war on which any real attempt to eliminate war must be based. So too in his chapters on science and education and on science and religion, we have a fine plea for educational research, for men with the divine gift of imagination, coupled with the inquiring mind that forces them into research, and men trained to appreciate, to apply and to expound the results of such research; and the conviction that the scientific method must be practised by men of goodwill whose faith in the end they serve is deep-rooted and firm. The hope of this civilization, Dr. Hill urges, lies in the discovery of men in whom the accurate thought born of a scientific training is imbued with the faith that moves mountains in all that is good and operates through a sense of service that outstrips all hope of reward.

Dr. Hill is liveliest in his final chapter on "Science and Leadership", where shrewd criticism of the weaknesses and limitations of scientific men is accompanied by a strong plea for their freer admission to positions of administrative responsibility, and for attention in their training to measures such as wider contacts and interchange of students and of staff which in the formative years contribute so much to widening their outlook. Despite their occasional lapses, Dr. Hill stoutly maintains that scientific workers are more likely to be objective in their judgments than most men, and that the combination of technical skill and knowledge with administrative ability is not rare. Finally, he drives home to scientific workers themselves the lesson that if they are to play their full part in human affairs, they must learn to express themselves adequately, abandon the attitude of aloofness and isolation, and recognize both the limitations of their experience and the importance of those considerations of quality in the realms of human relations, economics and politics, which their preoccupation with quantitative factors is apt to lead them to overlook.

R. BRIGHTMAN.

# SCIENCE IN THE U.S.S.R.: AN AMERICAN SURVEY

Science in Soviet Russia

Papers presented at Congress of American-Soviet Friendship, New York City, November 7, 1943, under the auspices of the National Council of American-Soviet Friendship. Pp. ix+97. (Lancaster, Pa.: Jaques Cattell Press, 1944.) 1.50 dollars.

AFTER the Revolution in Russia in 1917, the United States Government severed diplomatic relations and did not resume them until 1933. To commemorate the ten-year period a meeting of the Science Panel of the Congress of American-Soviet Friendship was held in New York City on November 7, 1943. It was in two parts: one section under Prof. Harold C. Urey dealt with Soviet science and technology, and the other under Prof. Walter B. Cannon with public health and war-time medicine in the U.S.S.R. Fourteen papers were read, each dealing with a particular branch of science, and they are collected in this little volume, "Science in Soviet Russia".

One of the authors, D. Wilder Penfield, of the Montreal Neurological Institute, McGill University, had the advantage of a recent visit to the U.S.S.R. as a member of the Medical Mission that went there in July 1943. He gives a very interesting and well-balanced account of what he saw. He found Soviet war surgery well organized, efficient and modern, and medical education established on a sound and adequate basis. The use of sulphonamides was well understood, as were also plaster treatment of wounds and fractures, provision of blood and blood substitutes for hæmorrhage and shock, and evacuation of wounded by air. The organization of the surgical work was especially good, though in certain refinements of technique there was room for improvement. Medical education has developed rapidly. In 1940 there were 160,000 medical practitioners; in the five pre-war years, seventy-two medical institutes had turned out about 21,000 new ones

yearly: before the War, 50 per cent were women; now the proportion is about 85 per cent. Like others who know them, Dr. Penfield speaks very highly of the efficiency of the Russian women. He praises, too, the nurses, who not only tended their patients but also helped build the huts in which they were to live and work, besides being attractive partners in the dance given to welcome the Mission to a forward hospital. He saw no signs of malnutrition: the ration, he was told, was 1·75 lb. bread daily and 4·4 lb. meat or fish weekly for a worker; and 0·8 lb. bread daily and 1·3 lb. meat or fish weekly for a non-worker or child working less than three hours per day. Prof. Winslow describes what he saw of the work on public health in 1936. The death-rate from diphtheria, the incidence of syphilis, infant mortality-rate and death-rate in the larger cities had all been greatly reduced since 1913, and medical services were being pushed out into the villages as personnel became available. Malaria and dysentery remained as major menaces, but rodent carriers of plague were being dealt with. The outstanding feature of the public health programme was the provision for the care of maternity and infancy.

Two papers were devoted to geology in the U.S.S.R. Dr. Muller mentions the conversion of coal *in situ* into gas, which is then piped directly to the furnaces of industrial plants. British men of science remember with pride that the original suggestion was made by Sir William Ramsay: it was quickly taken up by Lenin, who saw in it the possibility of improving the coal workers' lot; the story has been told by Dr. E. B. Bailey in the *Journal of the Royal Society of Arts* (92, 540; 1944).

Dr. Muller also gives an account of the work on "Permafrost", that is, permanently frozen sub-soil. Prof. Dunbar attended the Geological Congress in Moscow in 1937 and quotes figures showing the remarkable increase in mineral output:

| | 1921 | 1927 | 1937 | 1940 |
|---|---|---|---|---|
| Aluminium | — | — | 37,000 | |
| Copper | 2,000 | 12,000 | 92,000 | 125,000 |
| Pig iron | 112,000 | 2,900,000 | 14,520,000 | 15,500,000 |
| Manganese | 29,000 | 840,000 | 2,750,000 | |

Dr. Waksman deals with bacteriology in the Soviet Union, a subject on which he has encyclopædic knowledge. The great pioneers were Metchnikov, who worked on medical bacteriology at Odessa, and Siergei Winogradsky, whose investigations in general bacteriology were made at the Academy of Medicine, St. Petersburg. Subsequent developments in these directions are indicated, the names of the investigators and a brief statement of their contributions being given.

Dr. Stanley describes Soviet studies on viruses in an account which is the more interesting because he concentrates on a few important papers by Ivanovski, Rishkov and Goldin, and indicates only in a list of references the subsequent developments.

Brief sections on electrons and on soil and agriculture complete the book.

It is interesting to compare the American evaluation of the scientific work with the British. We should certainly have included a section on chemistry so as to include accounts of the work of Semenov, Frumkin and others, and mention would have been made of the mathematician Vinogradov, the physicists Joffe and Kapitza, the agricultural botanist Lysenko and the soil scientists Dokuchaiev, Glinka and Polynov. Yet none of these names occurs. The book has the same title as one by J. G. Crowther, published in 1930, and a comparison of the two shows something of the change in the last fourteen years. In some way or other, British scientific workers must learn more about what their Russian colleagues are doing. Admittedly the difficulties are considerable. It is too much to expect British scientific workers to learn Russian on any extensive scale, and it is unfair to Russian science to judge the papers solely by the short summaries in English given at the ends. Perhaps the best way to ensure a proper appreciation of the work would be to arrange for the publication of systematic accounts of specific subjects, somewhat on the lines of those issued from time to time by the Imperial Bureaux of Soil Science and of Plant Genetics, and of translations of specially important papers. E. JOHN RUSSELL.

# INDUSTRIAL HAZARDS

## The Analytical Chemistry of Industrial Poisons, Hazards and Solvents

By Dr. Morris B. Jacobs. (Chemical Analysis: a Series of Monographs on Analytical Chemistry and its Applications, Vol. 1.) Second revised reprint. Pp. xviii+661. (New York: Interscience Publishers, Inc., 1944.) 7 dollars.

WHETHER we work in office, shop or factory, with hand or brain, we are exposed throughout life to a number of hazards quite outside the powers of the police to prevent. Such hazards are detected by workers who wear no uniform unless it be the white coat of the laboratory, and come under the general heading of industrial hygiene. There is ever-increasing need for their watchfulness as industry and life grow more complex. Industrial poisons, gases, dusts, vapours of solvents, lurk around the corner ready to attack us once or repeatedly until we fall sick or lose our working efficiency.

The public has little knowledge of the extent to which they are guarded, while those who act as guardians are conscious of how much more remains to be done in the nature of staff and equipment.

Any new subject demands new methods; in general these have to be quick and simple. Hence the desire on the part of the author, who is senior chemist to the Department of Health in New York City, to bring together the analytical chemistry of industrial hygiene. He has produced a bulky volume, for such instructions, if they are to be explicit, have to be given in considerable detail. Workers in the smaller laboratories faced with the same multitude of problems as in a large city have little time to search for the best methods of attack or to devise new ones and will therefore be glad to have a book in which they are detailed.

The headings adopted for the detailed treatment are sampling—never an easy task—the measurement of gas volume and quantity, absorbers and absorbents. Then follows a description of the chemical and microscopic estimation of dust and silica, of the dangerous and other metals, of the common poisonous compounds of sulphur, nitrogen and phosphorus, the halogens, carbon compounds like carbon monoxide, hydrogen cyanide, etc. Further sections deal with organic compounds, particularly the growing class widely used as solvents. Lastly, the chemical warfare agents have to be considered, a necessary though tragic precaution in these days.

It would be unfair to criticize any of the methods on points of detail—they have all been tried out in the laboratory and serve their purpose. What is important is that their listing will save an immense amount of time for other workers.

Our life in the factory, even in travel to and from work, exposes us to hazards which we fail to appreciate until afflicted with some ailment which our medical adviser finds hard to diagnose. Acute poisoning is generally accidental and obvious, but the effects of slow and chronic poisoning are more deep-seated and often much more damaging. Once the causes are diagnosed and understood they can be removed, but to do this requires much careful work on the part of the chemist.

Chemical warfare agents are unlikely to be experienced in the United States as the result of enemy action, but during their manufacture and subsequent processing they do present serious risks. Many of them are hazards met in industry under another guise, either as industrial products like chlorine and phosgene, as by-products, or as decomposition products of other substances. It is a growing practice, for example, to transport chlorine and ammonia in tank wagons holding tons, or containers of several hundredweight capacity: a spill in transit might have most serious consequences, killing or injuring people over a wide area. A recent issue of a New York journal gave an alarming picture of an actual incident. 'Warfare agents' are also being developed for peace-time uses as fumigants, insecticides and even for extinguishing fires and refrigeration. A careful watch will have to be kept that rigid precautions are taken both in manufacture, storage, transport and use of such chemicals. In passing, it may be noted how few noxious chemicals are of any value in war: of more than three thousand substances tested less than a dozen were of any importance as warfare agents.

Incidentally this is the first of a projected series of monographs on analytical chemistry and its applications.

E. F. ARMSTRONG.

## CONTROL OF BACTERIAL ENVIRONMENT

### Micrurgical and Germ-Free Methods

Their Application to Experimental Biology and Medicine; a Symposium. Edited by James A. Reyniers. Pp. xiv+274. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas, 1943.) 5 dollars.

IN November 1939 a colloquium was held in the Laboratories of Bacteriology of Notre Dame University to discuss micrurgy, or microscopic surgery, the cultivation of plants and animals in the absence of bacteria, and the control of aerial cross-infection in hospital wards. The papers which were contributed are now published in an attractive book, profusely illustrated with good photographs and diagrams, with a common index at the end, and generous bibliographies for each contribution.

Three papers deal with micrurgy. James A. Reyniers describes and discusses the design of machines for making single-cell cultures of bacteria and spores. Various ingenious devices are presented; the paper is entirely technical. M. J. Kopak describes the technique of measuring surface tensions and the behaviour of oil-water interfaces inside cells by injecting small drops of oil into them through micro-pipettes. The hydrostatic pressure necessary to form the drop gives a measure of the oil-water surface tension. An oil drop formed at the point of a micropipette in a watery protein solution collects protein molecules in its surface; if the drop is sucked back into the pipette, the area of the surface film decreases and the protein molecules are compressed until a critical drop size is reached, when the compressed surface film wrinkles—the Devaux phenomenon. Observation of such drops in watery protein solutions, in disintegrated protoplasm and inside living *Arbacia* eggs, provides evidence concerning the state of proteins in living protoplasm—a subject which the author discusses. E. M. Hildebrand contributes a review of all the uses to which micrurgy has been put in botany.

The remaining eight papers deal with germ-free methods. Reyniers describes his system of closed apparatus in which germ-free vertebrates, born by Cæsarean section or hatched from germ-free eggs, can be reared, fed, watched and inoculated. Guinea pigs and chickens, completely free from bacteria, have been kept alive and healthy for six months. Two Rhesus monkeys were similarly raised; one died from an accident after forty-five days, the other was still alive and well after four months.

Oram C. Woolpert and N. Paul Hudson contribute a review of the use of the mammalian fœtus as an experimental animal in bacteriology, virology and immunology, and discuss the technique of intra-uterine inoculation.

R. W. Glaser, in a paper on the germ-free culture of certain invertebrates, describes methods of obtaining germ-free strains by multiple washing of Protozoa, or of the eggs or larvæ of worms or insects, with or without the use of bland disinfectants. Complex machinery is not needed. The chief difficulty is to devise suitable culture media on which germ-free strains can be grown. Certain Protozoa which are strongly geotropic can be made to swim clear of the bacteria which usually contaminate them. The germ-free method is particularly useful with certain parasitic species, cultivation of which in the past has generally failed on account of bacterial contamination. For example, germ-free cultivation of *Neoplectana glaseri*, parasitic on the Japanese beetle, *Popillia japonica*, has made possible mass cultivation of infective nematodes which can be used in the field to control the beetle. *Hæmonchus contortus* of sheep has been cultivated *in vitro* through some of its parasitic stages. Among insects, *Aedes ægypti* and *Musca domestica* can be bred indefinitely, by methods described in the paper, quite free from bacterial contamination.

Philip R. White discusses the cultivation of germ-free plants or parts of plants. The principles of technique resemble those applying to invertebrates. Sound aseptic practice is the main necessity, given which it is often possible to obtain uncontaminated cultures from growing tips, or from seeds in their fruits or pods, which are naturally germ-free.

The three remaining papers deal with control of the bacterial environment of man; or rather, with that of infants in hospital wards. James A. Reyniers describes a cubicle which he has devised in which infants can be raised without risk of aerial or contact cross-infection. By placing the infant in one cubicle, and the nurse who looks after it in another alongside, and controlling the ingress of bacteria to both cubicles by the usual aseptic methods and by regu-

lating air pressures so that the flow of air is always away from the infant, Reyniers considers that a mechanical system of barriers to cross-infection can be erected. I. Rosenstern and E. Kammerling describe an experiment designed to compare Reyniers' mechanical method of cubicle isolation with Wells' ultra-violet light barrier isolation method, and with ordinary air-conditioning as a control. Each system is being tested on a block of twelve cubicles at the Cradle, Evanston, Ill., the three groups of infants being comparable in point of age, general health, and respiratory infection rate. The result of the experiment is not recorded, but the authors give details of preliminary bacteriological tests made by spraying *Chromobacterium prodigiosum* into the air and following its distribution.

The last paper is a detailed description by William F. Wells of his method of reducing the bacterial flora of hospital air by means of ultra-violet light screens.

The greater part of all of the papers is devoted to technique, but the authors also discuss the many uses to which the methods they describe may be put.

## PRACTICAL MALARIA CONTROL

**Practical Malaria Control**

A Handbook for Field Workers. By Dr. Carl E. M. Gunther. Pp. 91. (New York: Philosophical Library, Inc., 1944.) 2.50 dollars.

THE title of this book is an ambitious one, and our appetites are sharpened by the reputation of the author as an entomologist of repute, one fully acquainted with the literature of malaria, with practical experience in the field, as well as in the laboratory. In performance, however, the result is a little disappointing. The style is somewhat involved and confused, and the author has failed to make the most of what is a great opportunity. Many of the statements are dogmatic and open to criticism. For example, it is recommended that in conducting a malaria survey the best method is to collect adult *Anopheles* and post them to the nearest school of tropical medicine, or even the British Museum, for identification. At this point the student is left entirely in the air with the advice that no useful purpose can be served by detailing special control methods applicable to individual species of *Anopheles* which constitute the whole basis of species sanitation.

Under personal measures, the author declares himself a zealous advocate of prophylactic quinine, and, because of the excellent results he has obtained, insists on its use by every member of the non-immune population more than ten years of age. For small children quinine prophylaxis is not advised, as tending to produce the typical thin, pale and languid 'tropical' child. It will be noted that distinctions are drawn between measures applicable to those who are immune and those who are non-immune to malaria.

The author's brief instructions on the control of malaria in military campaigns can scarcely be of practical value under present war conditions.

The clinical section suffers from generalizations, and no attempt has been made to distinguish clinical syndromes produced by different species of *Plasmodium*, but one can infer from the sense of the text that the subtertian form is the one with which the author is most familiar. In treatment the author is by no means enthusiastic about 'Atebrin'; he prefers intramuscular injection to oral administration. When given by the mouth 'Atebrin' is, he avers, erratic in action, while 10 per cent of patients are highly sensitive and suffer from poisoning which is marked by "racking intractible bilious vomiting" lasting 12–14 hours. The treatment of blackwater fever does not follow on generally accepted lines; there is, for example, no evidence that blood transfusion aggravates intravascular hæmolysis. P. MANSON-BAHR.

## THE BACKGROUND OF IMMATERIALISM

**Immaterialism**

Annual Philosophical Lecture, Henriette Hertz Trust, British Academy, 1944. (From *Proc. Brit. Acad.*, 30.) By Dr. A. A. Luce. Pp. 16. (London: Oxford University Press, 1944.) 2*s*. net.

IN this lecture, given before the British Academy, Dr. A. A. Luce comes forth as an explicit defendant of the doctrine that there is no such thing as matter. There are periods in the history of philosophy when immaterialism becomes fashionable. Bishop Berkeley, in his "Principles", and Collier, in his "Clavis Universalis", arrived independently at the doctrine in the early years of the eighteenth century. Dr. Luce's lecture throws great light on the intellectual soil which gives rise to such a doctrine.

Just as Berkeley started from Locke's position that "all our knowledge is by way of ideas", so Dr. Luce starts from the position of Moore, Russell and Broad—in principle the same—that all our knowledge is by way of sense-data. Hence he substitutes for the question "Does matter exist?" the question "Is there material substance *over and above the sum total of sense-data*?" The negative answer which he gives to the second question has no tendency to show that matter does not exist except to a believer in sense-data.

As soon as philosophers analyse experience into components, whether ideas or sense-data, matter cannot be found; it lingers on only until someone like Bishop Berkeley or Dr. Luce gets up to say that, as it cannot be found, it would be as well not to keep on talking about it.

But the fault may lie in the original analysis, which omitted something of importance. Dr. Luce says: "When in Boswell's presence Dr. Johnson kicked the mighty stone and 'refuted' Berkeley, he was simply appealing to what he could touch and see, i.e. to sense-data and *sensibilia*, and if that be all that is meant by 'matter', any reasonable immaterialist would accept it" (p. 6). This way of dismissing Johnson's refutation under-estimates the innate good sense of that mass of English judiciousness. It is possible that Dr. Johnson was appealing not to sense-data but to a quite different experience, namely, a direct awareness of another body opposing my body, in which the sensations of touch are merely episodes, featuring in, but not exhausting, the total experience. If so, this kicking of the stone was a valuable commentary on a missing element in all such theories as Berkeley's. Those philosophers who speak of sense-data as 'presented' to us or as 'presentations' forget this element and talk as though life was like a cinematograph film unrolling before us, instead of what it is and is felt by us to be, an interaction of bodies. If we surrender this point, we surrender matter. WINSTON H. F. BARNES.

## John Dalton

Some Unpublished Letters of Personal and Scientific Interest, with additional Information about his Colour-Vision and Atomic Theories. By Dr. E. M. Brockbank. (Publications of the University of Manchester, No. 287.) Pp. ii+62+5 plates. (Manchester: Manchester University Press, 1944.) Cloth, 7*s.* 6*d.* net; boards, 7*s.* net.

DR. BROCKBANK'S modest booklet, dated on the centenary of Dalton's death, does not bring forward any new material of primary importance bearing upon the philosopher's life and work; nevertheless, it will be welcomed by all who are interested in Daltoniana. It contains notes on Dalton's family history, on the Kendal and Manchester periods, on his appreciation of female society, and on his relationships with the Society of Friends and with Peter Clare, together with nine hitherto unpublished letters. There are also short chapters on colour-vision defects and the genesis of the atomic theory. It is revealing that Dalton found Boyle's style "so tedious and verbose" in his chemical tracts "that one cannot reap the full advantage from them, except they were condensed and digested a little better"; at the same time (1790) he regarded Boerhaave's "Elementa Chemiae", published in 1732, as "a capital" treatise, and approved also of the "essays of the present Bishop of Llandaff" (Richard Watson). Among other interesting details we may note that early in his career Dalton gave tuition for so little as a shilling an hour; that in 1792 he found London "a most surprising Place to a Stranger"; and that although he was often regarded as a gruff disciplinarian, somewhat uncouth or even morose in manner, yet in his younger days he used to write extempore verses in the diaries of his lady friends. J. R.

## International River and Canal Transport

By Brig.-General Sir Osborne Mance, assisted by J. E. Wheeler. (International Transport and Communications.) (Issued under the auspices of the Royal Institute of International Affairs.) Pp. viii+116. (London: Oxford University Press, 1944.) 10*s.* 6*d.* net.

INLAND waterways have always been important lines of communication and transport, and the tendency in recent years has been to increase their use by canalization and control of flow, as their value is enhanced by hydro-electric schemes. But this new value of flowing water raises many acute problems of international control, since the most important rivers are seldom confined to one State.

Sir Osborne Mance has rendered considerable service to the river problems of to-morrow by compiling a general survey of existing international river arrangements with special reference to Europe. These arrangements will not necessarily remain, but they indicate many of the problems that will shortly have to be faced. The Rhine, Danube, Elbe and Vistula are four rivers that are hedged around with problems of this nature, each being vital to the well-being of more than one State.

It is a pity that the pamphlet gives little or no account of the depths, flow, width and lock systems of the rivers and canals, since these considerations obviously affect the problem. There are two rough sketch-maps showing the main waterways, and projected canals of central Europe.

But surely the price is high for a pamphlet of little more than a hundred pages.

## The Application of Radiant Heat to Metal Finishing

A Critical Survey of the 'Infra-red' Process for the Stoving of Paints and Enamels. By Dr. J. H. Nelson and H. Silman. Pp. viii+79. (London: Chapman and Hall, Ltd., 1944.) 8*s.* 6*d.* net.

THIS useful little book is very rightly critical of the indiscriminate use of the term 'infra-red' to describe radiant heat sources, for one cannot but be amused to see a battery of brightly incandescent lamps referred to as an 'infra-red' lamp heating plant. After a short introductory chapter on radiant heat and its advantages, the authors describe the principles of heat transfer, giving the physical laws pertaining thereto and an elementary treatment of some of the mathematics involved. Thereafter, the study is essentially of a practical nature and includes the history of the 'infra-red' process, reflectors, plant construction and design, paint formulation and the field of application of radiant heating.

It is pointed out that while considerable progress has been made in the practice of radiant heat applied to the stoving of paints and enamels on metal surfaces, rapid developments in technique are to be expected in the very near future.

The book can be recommended to those needing guidance on the subject.

## Direction Finding by the Stars

By J. B. Sidgwick. Pp. 88. (London: Faber and Faber, Ltd., 1944.) 5*s.* net.

MR. SIDGWICK'S little book provides much useful information for those who have only a rudimentary knowledge or no knowledge of the constellations and chief stars. Starting with the Great Bear, which most people recognize, directions are given for finding and recognizing the other constellations which appear at the different seasons. The stellar bearings are easily found from a date table and a number of graphs, and the use of the table and graphs is illustrated by examples which are fully worked out. Even the novice should find no difficulty in applying these to obtain his bearings if he carries a copy of the book in his pocket. In addition to finding one's bearings, directions are given which enable the reader to determine the time by means of the sun and a number of the brighter stars. Soldiers on active service will find much useful information in the book. M. D.

## Good Soil

By S. Graham Brade-Birks. (Teach Yourself Farming Series.) Pp. 296. (Bickley: English Universities Press, Ltd., 1944.) 3*s.* net.

SOMEWHAT more academic than are other volumes in this series, this book covers a good deal of ground in small compass and presents an invaluable introduction to soil science—though possibly the section on cartography could have been fuller. The book is especially notable as making accessible the details of Dr. Linwood L. Lee's New Jersey method of recognizing textural groups by handling the soil, for its numerous and instructive illustrations, and for its useful outline of soil mineralogy. The book pays special attention to soil texture, describes world soil groups ("the soil-pattern of the world"), and has a practical chapter on finding the best crop for every soil under English conditions.

It can be cordially recommended to biologists and non-biologists as a clear exposition of a subject about which few books exist.

# FUTURE OF BIOLOGY IN WORLD AFFAIRS*

By Dr. FRANS VERDOORN

DURING the last months of the War of 1914–18, a period which—from many points of view—may be compared with the present, the plant scientists and zoologists of the world were less involved in the war effort than they are to-day. Nevertheless, as such addresses and papers as Lyman's "Contributions of American Botanists for More Active Prosecution of War Work" (1918) and Stevens's "American Botanists and the War" (1918) show, some of the foremost plant scientists of the United States were prevailing upon their colleagues to engage in activities which might help the war effort. At the same time much consideration was given to the War from a biological point of view, as such publications as Nicolai's "Biology of War" (1919) and Pearl's "Biology and War" (1918) testify. Just before the end of the War many interesting papers on the role of botany and biology in the post-war world were published. These included "Botany as a National Asset" (Coulter, 1917) and "Botany after the War" (Davis, 1918), and were followed by an unusual number of inspired discussions by men like Lyman, Peirce and Gager. Though during those years a number of biologists did accomplish useful things in such fields as pioneering in dehydration, raising the agricultural output and discovering substitutes of vegetable origin, the foremost trend of thought, especially in the Allied countries, was concerned with biology in the post-war world, in human relations as well as in agriculture, etc. The Germans of that time were, comparatively, much more concerned with problems directly relating to the war effort than were their colleagues in the Allied countries. Diels wrote an entire volume on botanical substitutes; Haber and other chemists revolutionized the fertilizer situation.

In the discussions in Allied countries the educational and humanizing value of biology was stressed much more than it is to-day. Many believed that a better knowledge of, and better training in, biology might well revolutionize the citizen's attitude towards essential problems of life and human relationships. This hope has not materialized—and that, without doubt, is a reason for the sceptical and negative attitude of many of us to-day.

In one field, however, enthusiasm, understanding and leadership on the part of the biologists of the Allied countries was scarcely progressive. It strikes the historian as strange that in those Wilsonian years very little was said, in either British or American discussions, about international work and relations in science, the re-establishment of international relations, etc. There was a much more patriotic (though not a soundly patriotic) tone in the discussions then than there is to-day, when it looks as though groups of men of science (not necessarily natural scientists) in Great Britain and the United States are at least as much interested in post-war international relations as are the large political groups. It was in 1919 that Livingston turned down Lotsy's generous offer to combine the planned *Botanical Abstracts* with the *Botanisches Centralblatt*, at that time—in spite of its name—a purely international journal and the official organ of the now defunct International Association of Botanists. This rejection killed that Association and much that it stood for, and postponed for years a resumption of international relations work in botany, so enthusiastically started before the War of 1914–18 by men like Scott, Goebel, Farlow, von Wettstein, Trelease and many others.

When war broke out in 1939, international relations work in science had not yet fully recovered, nor by any means reached the status of 1914—this in spite of the many congresses, meetings and commissions in our field about which I have reported in great detail, in an effort to stimulate interest in them, in special sections of *Chronica Botanica*, volumes 1–3. Reading those reports of the years before the present War and comparing them with those during 1912–14 creates the conviction that an unsound impetus was given during the years just before this World War by motives only slightly differing from national propaganda.

In this War the biologist has played a much larger part than in any previous war. Botanists, agronomists, zoologists, entomologists, psychologists and bacteriologists have contributed in larger numbers and in more intensive ways than ever before to the war effort. Men of science form one of the few groups in society which know that the concepts and ideas by which politicians and the accepted organizers of human relations are guided are mostly wrong, based on misconceptions, old superstitions and false intuitions. Yet the man of science has left not only the administration, but also most of the study, of the administration of human life and world affairs in the hands of people who are not very appreciative of what a century of progress in the science of life has achieved. Therefore, I cannot help feeling that men of science are more truly responsible for the chaos of to-day than any other part of society.

The resources, strength and endurance of the United States, the British Empire and the U.S.S.R. and their allies are bringing this War to an end, an end which will place the man of science once again in a very favourable position, as he will remain free in the post-war world, not in all but in much more than half of the Allied territory. How will he use this freedom of thought and action?

I want to begin a discussion of the peace tasks of the man of science with a most difficult problem, which logically does not come first at all. Yet it is so important and most of us are so consistently dodging it that I feel I must bring it up before anything else.

When we speak of the re-establishment of international relations, I believe that most of us think primarily of Great Britain and other Allied countries. Most of us do not think clearly about *the re-establishment of relations with the present enemy countries*, especially with Germany. Yet there can be no doubt that it is essential that workers in science, the humanities, and the arts understand that they are the members of society best fitted to pioneer in the re-establishment of relations with the enemy and that it is necessary for them to prepare to do so at short notice. Intellectual life, as Raymond Fosdick has said, is the most fundamental unity of modern civilization, and that life cannot be broken in parts without disaster. This is the most obvious reason, clear to anyone, for a demand for a quick and thorough re-establishment of international relations

* From an address entitled "The Plant Scientist in the World's Turmoils", contributed by Dr. Frans Verdoorn (of Arnold Arboretum and editor of *Chronica Botanica*) to a symposium on "Biologists and Rehabilitation" held by the Botanical Society of America and the American Association for the Advancement of Science at Cleveland, Ohio, on September 13.

in science and the humanities. But there is another reason with which not everyone may agree as quickly but which seems to me at least as important. Peace, progress and human well-being generally depend upon the integration of present enemy countries in some system of full international co-operation. Biologists know that our world needed millions of years to develop to its present status and that it will need some time to develop into a commonwealth of nations. Yet the trend of the development of mankind is in that direction, and the groups best fitted to do so have to go ahead and assume leadership. The necessity for this was expressed in more detail already early during this War by a manifesto of fifty-seven members of the Royal Society of London. It is the duty of the men of science to the world—and therefore also to their own countries—to re-establish relations with enemy colleagues *both* individually and through meetings, congresses and international commissions, *in all fields* (also where the activities of many Allied research workers are controlled by trusts) to the fullest possible degree and as soon as circumstances permit. We must do this whatever practical commands for dealing with Germany, German split States, etc., may be, in order that the German man of science will not 'go underground'. The world of science needs him, but the world at large needs him still more. The mistakes made after the War of 1914–18, when most international co-operation in science was started in France, more by politicians than by men of science, and restricted to Allied and neutral countries, must not be repeated, even though we know that some of our enemy colleagues will use purely scientific co-operation for other purposes.

To enter again into mutually useful relations with colleagues in enemy countries, it will be necessary to realize that some of them think as we do, but many of them do not. To deal with these men it is necessary to realize that the Totalitarian State, in which the younger ones especially believe and may continue to believe, is a form—evil, we may think—of world evolution. It has enabled men, men of science, social workers and others to do things in science, research, teaching, social applications, etc., which are not necessarily evil—as is often tacitly assumed only because they were made possible by a Fascist Government. Especially in the biological and agricultural sciences much that was excellent was done during the pre-war years in the Axis countries. Study, understanding and realization of these things is a necessary basis for a good programme of the re-establishment of relations, 're-education', etc. The politician, let us never forget, has to emphasize what divides; the man of science may well emphasize what unifies. Workers in pure and applied biology are in a specially favourable position to pioneer in this field. The problem of intellectual relations with Germany demands more than goodwill; it asks for effort and study.

Speaking of agriculture in the post-war world, Dr. Auchter, of the U.S. Department of Agriculture, in a recent address emphasized (1) improved nutrition for human beings, (2) methods of breeding and the use of substances that regulate growth, (3) world exploration to obtain and maintain material for breeding purposes, (4) the changed fertilizer situation, (5) utilization of waste and by-products, and (6) problems of insect and disease control. To them I should like to add research in a field about which we heard more at the end of the War of 1914–18 than to-day. In spite of the lack of emphasis on international relations at that time, there were in the minds of our colleagues, a generation ago, a number of ideas, or rather a feeling, for the necessity of closer relations between science and government (not necessarily human politics). We might call this borderland biopolitics. I miss a plea for it to-day. Is it because we have despaired of ever establishing such relations? Or is it a reaction against the close relations between biology and politics in the U.S.S.R. in which biology has occasionally been reduced to serfdom? If that is so, a word of warning must be expressed. To do so I just used the word *biopolitics*, which will recall a related field of research, *geopolitics*, developed by and first used in the Axis countries, but, once again, not evil on that account, as shown by the ways it is now being developed along purely scientific channels by American scholars. Biopolitics and geopolitics may well be the ways along which men of science will find it possible to reach those groups which they hitherto failed to influence.

It is not true that the two World Wars are simply conflicts between have and have-not nations; yet the conflicts between these two groups are more responsible for the twentieth century chaos than are any other conditions. The practical politician will deny this vehemently; the man of science knows better. H. G. Wells in 1940, in "The New World Order", considered it the second most important of the four major causes of war. The man of science, the only reliable authority on natural resources and the possibilities of their development, may well contribute a major share to the establishment of a durable peace. He also knows that a durable peace will have to be plastic—a consideration which the practical politician again considers absurd.

One of the resolutions of the United Nations Conference on Food and Agriculture states: "The natural sciences are a particularly fruitful field for international co-operation because they are themselves international; basic physical and biological laws are the same anywhere and universally accepted". This is true, but it is also true that co-operation demands an attitude which is not typical of the average biologist. Considering the matter psychologically, most of the better workers in botany and zoology turned to this pursuit because early frustrating experiences resulted not in the normal, human response of aggression, but in a desire for isolation. It is perhaps a bit hard to demand now that these men become enthusiastic co-operators. We will, however, have to assume that at least some of them have learned that even in a Nature research it is true that 'united we stand, divided we fall'.

Sometimes I speak of plant scientists, sometimes of biologists, sometimes of botanists. This inconsistency is not due to carelessness, but to a tragic fact, to the greatest professional problem we have: there are no longer biologists or even animal scientists and plant scientists.

There was a discussion some months ago in the columns of *Science* about whether there still exists to-day such a subject as biology. Some of the writers stated that it was a fraud to speak of biology any longer, as we always mean something else. There is, of course, such a subject as pure biology when considered from a purely scientific or philosophical point of view, but there are no longer professional biologists. There are only specialists in the various branches of the pure and applied plant and animal sciences. What makes it bad is that these specialists do not keep together or think and plan together

with reference to their professional interests as medical and chemical workers do. Though very large in number (22 per cent of the men of science included in "American Men of Science" (ed. 7) are "Biologists" *sensu antiq.*), our position both as a group and as individuals is extremely weak. As wage earners we are in many cases not able to give our families the comforts and education which we received in our youth or which the families of our friends in college receive; as men of science we have either to teach or to work in applied biology, with the result that many branches, especially of descriptive biology, have an anachronistic status; as a group we cannot exercise an influence commensurate with our knowledge.

*Mutatis mutandis*, this situation is the same all over the world. From this it appears that the situation is the result of internal factors, and that it cannot be changed easily, for example, by establishing professional biological societies, unions, etc., especially not so long as—another curse of biology—its great men of science continue to refuse to give professional guidance.

With every generation an increase in specialization seems to become necessary. This may be really essential, but the result is that many workers spend their enthusiasm and greatest mental output in their youth, and end with years of not-too-inspired routine research. Great as the literature and body of facts of any branch of biology may be, I do not agree that all this specialization is necessary. The organization of most of our institutions is such that it forces the so-called free worker into a steady and dull routine.

We all, but the administrators of research especially, should distinguish between deep and permanent specialization. But even if we feel that permanent and deep specialization is necessary, can we not educate our pupils with the feeling that they are in the first place biologists, whatever they do, and specialists in some branch of the pure or applied plant or animal sciences in the second place? No improvement of the status of biologists is possible if they do not recognize the very close interdependency between pure biology and applied biology on one hand, and between biology and world economy and government on the other hand. Also all biology, in contrast to physics, mathematics, etc., continues to have close ties with the humanities. We cannot fulfil our mission if these facts are disregarded; we cannot raise a satisfactory crop of young biologists if we and they are not governed by this knowledge.

Now let us consider the aims of international co-operation in science:

(1) The exchange of information (scientific, professional and practical) in such a way that it will be available to anyone who can profit by it.

(2) The attainment of objectives which individuals or men of science of a single institution or nation cannot accomplish. These may be either in pure or applied scientific research, or they may be co-operative scientific or practical publications.

(3) The forming of an *esprit de corps* which may, at least at some time and at some place, counteract the evils of human international politics and contribute towards the establishment of a commonwealth of nations.

How can we best accomplish these aims?

(1) By the oldest and most important form: the publication of original research, in which every man of science takes part, uninterrupted even by war, every time he has an article or a book published. I find an increasing assumption that scientific publications, not research or knowledge, are the most important thing to-day. We all know that the number of publications is increasing more rapidly than our real knowledge. In two fields with which I am familiar enough to express a judgment, bryology and history, about half the papers of the last forty years have brought only material that needs revision, checking or completion, and that does not really, or only very immaterially, add to our knowledge. Many workers in these fields die without ever having contributed anything to the real advancement of their chosen field. A single monograph, a single well-planned handbook, could have been prepared in the same time now wasted on many little papers. Unfortunately for many of us, the question no longer seems to be how to contribute best to the advancement of science (the fact that many of us can contribute better to our science as a whole by various forms of organizing work is also too often forgotten), but how to make the best impression.

(2) By abstracting journals, international as well as regional.

(3) By international congresses and meetings.

(4) By international societies or commissions, responsible for the organization of international co-operative research. In biology most research is individual, or at most institutional; whereas in other fields of science, for example, astronomy and geodetics, research has developed markedly along lines of direct co-operation, national and international.

Though it is clear that most research in biology will remain quite individual (this should be recognized as the cause of the comparative lack of interest of many foremost biologists in international relations work), there are many scientific and especially applied scientific problems which could more easily and better be solved by some form of international co-operation. In taxonomy, for example, the terrible status of exotic cryptogamic taxonomy cries for some kind of concentrated attack; in plant pathology, a study, on an international basis, of the methods of disease control is greatly desired; in horticulture, an international centralization and further experimentation on the results obtained by the use of hormones in propagation has been asked for by the Permanent Committee of the International Horticultural Congresses.

(5) By international societies or commissions responsible for the organization of practical international activities. In botanical and zoological nomenclature the need for such co-operation was felt at so early a time that much has already been accomplished in this field. There are, however, many other things which could and should be done in the same way: the unification of botanical terminology, colour codification, etc. Such work as has been initiated by Prof. Record's International Association of Wood Anatomists could usefully be done in many other fields. A special war-time problem—and an immense one—is the reconstruction of herbaria and botanic gardens destroyed during the War; this is an international, not a national, task.

(6) By publications not reporting the results of scientific research (either in original form or in abstracts), but bringing together various kinds of information and intelligence. In some cases these may be only stimulating; in other cases, of direct use for the research worker. Publications of this type have played a great part in biology; and I have always been especially interested in them. We may distinguish:

(a) Address-books, either the old-fashioned lists of research workers or the more modern combination of such lists with a census of current research.

(b) Indexes of various kinds; for example, the *Index Herbariorum*, started by Dr. Hitchcock and now actively continued by Dr. Lanjouw.

(c) Such journals as the early *Botanische Zeitung*, early *Botanical Gazette*, *Dörfleria*, the *Chronica Botanica* when it was published as an "International News-magazine". Such journals which bring together various kinds of information and intelligence, discussions, notes, news, etc., have in the past always been published by individuals who after some time could not continue to give them the necessary time and money. They should, of course, be the official professional organ of an international society.

(d) A very great need exists also for a new and complete guide to the literature of the plant sciences. This also will be possible only with international co-operation.

(e) Then there are many publications, semi-scientific, semi-practical, like the "Index Kewensis" and "Index Londinensis" and my planned "Index Botanicorum", which were formerly compiled on an institutional or national basis, but which, in the future, will probably ask for an international effort.

None of these things in itself is very important, but together they make a complex mass of activities both inspiring and helpful, and well worth the effort, even if we realize that to do this work well some of those who will do it will have to give up projects in pure research dear to their hearts.

Just as a commonwealth of nations, the goal of almost all thinking men, is not yet in sight, it is clear that the time for some of the activities just enumerated is not yet here. The tendency of human development, in any field whatever, is, however, toward greater unity. Before there can be anything like a world-embracing commonwealth of nations, regional commonwealths may be more immediately feasible. Pan-Europe as planned by Briand and Coudenhove Kalergi is one of them; a united Western Hemisphere as planned by Simon Bolivar and Henry Clay, and to some degree established by Sumner Welles, is another. One does not have to be very familiar with international politics and relations to realize that a united Western Hemisphere is one of the greatest conceivable guarantees of a durable peace. Unfortunately we have learned during the past years that differences in race, temperament and economic interests make a united Western Hemisphere—which, at no time, seemed too Utopian—not so easy to accomplish.

Here the biologist meets opportunities such as he has never, if ever, met before. Agriculture, biology and medicine are fields in which Inter-American co-operation has an opportunity to do things so great that no one can question their usefulness and need; moreover, they are things which have a very strong bearing upon Inter-American economic and political relations. Though many of us in the countries of the Western Hemisphere realize these simple facts and this dramatic opportunity thrown in our lap, not too many of us seem aroused, in spite of the support of the Government and our large foundations. Is it due to the intuitive reluctance of the man of science to get mixed up in Government projects? Among biologists all over the world there is a feeling that relations with government (I do not mean any specific political group) should be avoided whenever possible. This may be a sound attitude from the point of view of pure research; from all other points of view it is a mistake. It reveals poor ability to read the signs of the times. Who should know better than the biologist that with the development of organisms their ecology becomes more and more intricate?

The structure of human society has become so complicated that it can no longer function well without regulation. This is not a political creed; it is a fact which we can observe all over the world. The government—to use a simple colloquialism—is there to stay, and we biologists should make of this opportunity what we can. Let us hope the biologist may see his opportunity and duty, for never before has he been in such a position to influence with simple means and little, if any, sacrifice the course of development of the Western Hemisphere directly and the world at large indirectly.

Much has been written during the past years about the form, aims and scope of inter-American co-operation in the pure and applied, plant and animal sciences. I will restrict myself to a few remarks and desiderata:

(1) Co-operative studies of the flora and fauna of tropical America are necessary, and more workers must be found for this work, even if it means some discontinuance of research of the Old World tropics.

(2) Students must be exchanged on a much larger scale.

(3) The problem of a common language must be solved in some way. Very probably it will find its solution best if the Latin American men of science make an increased use of English in their scientific publications and correspondence abroad. Their North American neighbour, however, must be able to read Spanish, both to understand the publications of his Hispanic colleagues and to appreciate their culture, which differs considerably more from the North American than, for example, the British or Scandinavian.

(4) An inter-American professional biological journal, with articles and notes in the three languages, if possible backed by an inter-American biological society, seems desperately needed to establish a common meeting ground.

(5) An inter-American biological station of the Woods Hole type, somewhere in Latin America, could do much good, especially if organized by biologists and agronomists, on a truly inter-American basis. It is very sad that the Inter-American Institute of Agriculture has not been organized by representative men of science. With the same means and effort something better could have resulted. But the biologists of the Americas are also at a fault for having watched (or not having watched at all) the development of this Institute with such an utter detachment.

I have devoted much space in my *Chronica Botanica* for the past few years to the promotion of inter-American relations and will shortly issue a volume entitled "Plants and Plant Science in Latin America". A single individual, however, cannot do very much. An inter-American biological society, an inter-American biological journal, and an inter-American biological station are needed; the latter will assure us of more satisfaction than merely a pleasant scientific holiday.

The biologists of the United Nations are, or will soon find themselves, in a truly unique position.

Some of them will have the opportunity of assuming leadership in the conduct of international relations work, with its profound implications.

A group of them can be instrumental in assisting in making the Western Hemisphere strong and influential, one of the least Utopian guarantees of a durable peace.

Further, they will all be in a position to assist with the creation not of a planned supreme State, which is the criterion of all values, but of a government of free responsible men, which will guide human relations and world affairs according to the laws of living Nature, as discovered and set forth by biologists.

## CONSTITUTIONAL ISSUES IN SOUTH-EAST AFRICA

By PROF. DARYLL FORDE
International African Institute

THE recent announcement by the Secretary of State for the Colonies concerning the establishment of a standing Central African Council for the three territories of Southern Rhodesia, Northern Rhodesia and Nyasaland represents a further step in the attempt to secure an orderly solution of economic problems and political issues that have been intensified by the War. These three contiguous territories, each with an African population of about one and a half millions, share in varying degrees the problems that arise from the introduction of Western technology and white settlement in Africa. The issues are, however, by no means identical in each territory, and these differences, together with a conflict between the British Government and local white sentiment over long-term native policy, present serious obstacles to satisfactory constitutional development.

Southern Rhodesia, with a European population of about 69,000, has had virtual Dominion status since 1923, and its executive government is responsible through the legislature to an electorate practically confined to whites. Although its constitution reserves to the Secretary of State for the Dominions considerable control over native affairs, this is of limited practical effect. The segregation of the native population and their exclusion from some occupations, in order to protect Europeans from native competition, are, as in South Africa, avowed objects of both the Government and the European population.

A substantial majority of the white population of about 13,000 in the Protectorate of Northern Rhodesia, most of them directly or indirectly dependent on the mining industries, share the sentiments of the white Southern Rhodesians. Despite the absence of any legal sanctions and the positive legislation of the Protectorate, they too are able, in practice, to impose restrictions on the employment and status of the native population.

In the Protectorate of Nyasaland, on the other hand, with a small white population of less than 2,000 planters, the principle of trusteeship and "the paramountcy of native interests" which is accepted by the British Government and so widely endorsed in Great Britain meets with less effective local opposition.

The whole problem is still further complicated by the fact that a very large proportion of the African male population, amounting to more than 100,000 in each of the territories, is employed as migrant labour on European farms and mines away from its native settlements. This has not only produced serious dislocation in native agriculture and community life, which is bitterly resented by champions of the African cause, but also, since there is a large-scale migration of labour across frontiers, calls for co-ordinated action in all the territories concerned.

The Southern Rhodesia Government has, over a number of years, pressed for the unification of the three territories under a responsible government which could, among other things, deal with the labour problems of the area as a whole. The evidence given to the Bledisloe Commission of 1938 revealed strong native opposition to amalgamation on which the Commission itself could not agree; but the impact of the War and the contribution of the white peoples of Africa to the defence of the Empire have sharpened the issue. The regional grouping of colonies in the interests of technical development and administrative efficiency has gained increasing support, while General Smuts, in his speech at the end of last year, claimed for the Dominions a larger share of responsibility for the colonial territories in their respective spheres—in other words, the increasing influence of South Africa in the development of the southern African territories. The Prime Minister of Southern Rhodesia, Sir Godfrey Huggins, had earlier secured an undertaking that the question of amalgamation should not necessarily be postponed until after the War; while to meet the urgent needs of production and supply during the War, the Governors' Conference of these three south-east African territories has been supplemented by a joint secretariat.

The British Government now proposes to set up a standing Central African Council with a permanent secretariat, to deal with matters of common interest to the three territories. While only consultative, it is designed to provide machinery for the permanent co-operation of the administrative and technical services of the three Governments in such fields as industry, agriculture, labour, education and medical services. It is intended, in the words of the statement, that "leading unofficials in Southern Rhodesia and Nyasaland should be closely associated with the work of the Council", and it is recognized "that the Southern Rhodesia Government still adhere to their view that the three territories should be amalgamated". Amalgamation is, however, regarded as not being practicable "in existing circumstances", which, as Colonel Stanley explained in answer to questions in the House of Commons, refers not merely to the continuance of the War but also to "the difference in African policy between the territories".

At the same time it is proposed to take a further step forward in the constitutional development of the Northern Rhodesia Protectorate by increasing the unofficial membership of the Legislative Council from one to five, of whom three will represent the interests of the African community. The statement declares that "it is intended that African interests in the Legislative Council should be represented by Africans as soon as a suitable basis of representation can be built up", and the British Government is looking to the recently established Provincial African Councils as a political nursery for this development. This announcement concerning Northern Rhodesia, together with the express limitations on the powers of the Central African Council, makes it clear that the British Government still seeks to promote the growth of an educated and politically experienced African population which shall play its part in government.

# APPLICATIONS OF D.D.T.

TYPHUS can upset the plans and frustrate the might of the most powerfully armed forces. During the War of 1914–18 it killed some 10,000 people in six months in Serbia; after the Russian Revolution it killed some three million Russians. It has been recorded that during the siege of Granada and in the Thirty Years' War and the campaigns of Napoleon, it killed more people than the military weapons then in use. A disease which frequently attacks starved and disorganized populations and flourishes in times of national disaster, it broke out in Spain in 1908 and again in 1941, and it is a constant problem in the South American States and elsewhere. It has to be watched constantly, and the pages of the *Tropical Diseases Bulletin*, the *Bulletin of War Medicine*, the *Boletin de la Oficina Sanitaria Panamericana* and other medical journals record the work that is being done on all its aspects.

Epidemic typhus is caused by *Rickettsia prowazeki* transmitted rapidly from man to man by head and body lice. It should be distinguished carefully from endemic typhus, which is transmitted from rats to man by the rat flea. The old epidemiological rule "no lice, no typhus", quoted by the *Lancet* (115, July 22, 1944) still applies to epidemic typhus, and the best method of control is to attack this link in the epidemiological chain. Until recently, the lice have been attacked by heat and fumigation, and the organization and conduct of delousing stations has been no easy task, especially when large populations have had to be deloused. These methods, moreover, do not keep a population free from re-infestation with lice, which quickly occurs. Until comparat vely recently, no insecticide was known which would keep a person free from lice for longer than two days or so. Early in this War, work was undertaken to find new insecticides. A general review of the discovery and properties of D.D.T. was contributed to *Nature* of September 16, p. 352, by Prof. J. W. Munro. The story, so far as it concerns typhus, is briefly told in the *Lancet* (115, July 22, 1944) and the *British Medical Journal* (217, August 22, 1944).

Early in the War, British scientific men produced an insecticide called AL 63, which protected persons from lice for five–six days when it was dusted on to their underwear. Organic thiocyanates sprayed on to underwear protected the wearer for a month and could also be used on a belt so devised that it attracted the lice and then killed them; but these thiocyanates caused smarting when those who used them began to sweat. When the United States entered the War, teams of workers were put on this problem, and a dust called MYL was produced (*Soap and Sanitary Chemicals*, 105, November 1942), which was recommended by the U.S. Bureau of Entomology and Plant Quarantine. Russian workers had, in the meantime, developed two synthetic compounds, a powder containing diphenylamine, which was successfully used on civilians in Moscow (Fedder, M. L., *Gigiena i Zdorov'e*, No. 10, 12; 1942; quoted by the *Lancet, loc. cit.*) and *bis*-ethyl-xanthogen, with which garments worn by Russian soldiers in Bessarabia were impregnated (Gorkina, A. N., *Med. Parasitol., Moscow*, 11, 90; 1942; quoted by the *Lancet, loc. cit.*). Then came the discovery that the synthetic compound 2,2-*bis* (parachlorphenyl) 1,1,1,-trichlorethane), which has been called D.D.T., from the generic name dichlor-diphenyl-trichlorethane, has insecticidal properties of considerable promise. D.D.T. was first synthesized by the German chemist O. Ziedler in 1874 (*Deutch. Chem. Gesell.*, 7, 1180; 1874). Its insecticidal properties were apparently first made known by Paul Müller in Switzerland, when he reported his work with it on moths, flies and plant lice. In 1940 the Swiss firm of Geigy and Co., of Basle, patented it. Preparations of it are available under the name "Gesarol", either as a spray containing 5 per cent of D.D.T. with a wetting agent, or a dust containing 3 per cent of D.D.T.; another dust, called "Neocid", containing 5 per cent D.D.T. was produced for treating human lice.

Methods of manufacture were quickly improved and the toxicity of D.D.T. to a large number of insect pests, as well as to human lice, has been tested. An account of this work has been given by P. N. Annand and his co-workers (*J. Econ. Entom.*, 125, 37, February 1944), and the earlier work done with D.D.T. in Switzerland and Germany is there noted.

Annand concludes that D.D.T. is "one of the more promising synthetic organics" for the control of insects—a sober statement which should be borne in mind in these days when publicity is apt to exalt new discoveries far beyond the claims made for them by scientific workers. A reaction of some insects suggests, Annand says, that it acts as a nerve poison. It is distinctly toxic when it is dissolved in solvents such as oil, which can penetrate the skin, or when it is ingested; and more work is needed on its toxicity to man and animals. Appropriate precautions should therefore be taken by personnel who employ it as a dust likely to be inhaled or swallowed or in oily solvents. But in the concentrations in which it has been used for the control of human lice, it is apparently safe if reasonable precautions are taken: in these concentrations it does not appear to irritate the human skin.

D.D.T. is a crystalline solid, practically colourless and practically odourless, which results from the interaction of anhydrous chloral and chlorobenzene in the presence of concentrated sulphuric acid. It is insoluble in water, but soluble in most organic solvents. It is 'rather stable' and its volatility is low, so that loss of it from spray deposits is too slow to decrease its activity appreciably.

The tests of its action on human body and head lice and also on the human crab louse recorded by P. N. Annand (*loc. cit.*) indicate that it is highly effective and that its action lasts longer than that of any other louse treatment. It is better than MYL. It can be used as a powder diluted with kaolin or pyrophyllite, and such powders will protect grossly infested persons against lice for two to three weeks and will give effective control of lice for longer periods. It is equally effective against head or crab lice. The powder can be blown up the sleeves or down the necks of dressed persons, and this was done in controlling the outbreak of typhus earlier this year at Naples. The method is quick and has enabled the Naples authorities to treat a maximum number of 73,000 persons in a single day—a feat which could not be equalled by any other method. Another way of using it is to impregnate undergarments with it by dipping them in a solution containing D.D.T. in volatile solvents or in aqueous emulsions containing it. Both methods are good for either cotton or woollen garments. It is claimed that such garments will protect their wearers for three to five weeks without washing. Garments washed once a week protect for two to three weeks, or with stronger solutions for five to six weekly washes. Even stronger solutions will

protect for nine weekly washings. For the troops, a solution rendering garments protective for six to eight weekly washings has been recommended, and arrangements for large-scale treatment of such garments have been made.

Apart from its value for the control of typhus, D.D.T. may prove valuable for the control of a wide variety of insect pests. Annand and his co-workers (*loc. cit.*) report the results of their tests of its action on the bedbug, the house- and stable-fly, ticks and fleas of dogs, goat lice, "German" cockroaches (*Blattella germanica*), ants and termites, larvæ of the house-fly and numerous plant pests. For the control of the larvæ of malaria-carrying mosquitoes it is being tried as an emulsion sprayed over waters containing them, and the method of spraying it from the air is also being tried in an attempt to kill mosquitoes infected with malaria in areas in which troops have to operate. For the control of some species of cockroach it certainly seems to be effective. Recently an appeal reached the writer from a Manchester hospital for some means of exterminating a pest of 'steamflies' (*Blattella germanica*) on the hospital premises; Dr. H. Hurst sent a supply of a preparation containing D.D.T. and pyrethrum, with very good results. J. M. Ginsburg records (*J. Econ. Entom., loc. cit.*) the results of his experiments on the action of D.D.T. on this species of cockroach, which is a growing and serious pest in various parts of North and South America. Ginsburg found that the minimal concentration of D.D.T. required to kill 100 per cent of these cockroaches in jars in 48 hours was 7 per cent, while 33 per cent of sodium fluoride was required to kill 100 per cent of the cockroaches under the same conditions. In the same time a dust containing 33 per cent of derris killed only 30 per cent of them, while a dust containing 33 per cent of pyrethrum killed 90 per cent. If D.D.T. is as toxic as this to *Blatella germanica*, the work now being done on its action on locusts should be interesting.

Much of the work on D.D.T. is summarized by V. H. Chambers, G. L. Hey and N. K. Smitt, of the Murphy Chemical Company, Wheathampstead, in a reprint of an article in the *Market Grower* (62 Doughty Street, W.C.1—the date of the issue of this journal containing this article is not given). These authors refer to the work with D.D.T. done in Switzerland by R. Wiesmann (*Schweitz. Z. Obst.-u. Weinbau*, **51**, 155, 206, 245 and 329; 1942) on its effect on bees and fruit and vine pests and (*Anz. Schadlingskunde*, Berlin, **19**, 5; 1943) on flies in cowsheds. These authors also describe their own work with D.D.T. in the form of the Murphy Chemical Company's proprietary spray called 'DeDeTane' and with this Company's other preparations of D.D.T. Encouraging results were obtained against caterpillars of the tomato moth and against the grain weevil and the apple blossom weevil. 'DeDeTane' was, however, not so effective as nicotine against the apple sawfly, and it failed to control the plum leaf-curling aphis. Its possibilities as a means of controlling other insect pests are discussed, and the American work is summarized. D.D.T. may, according to this article, partly replace pyrethrum in the aerosol 'bombs' widely used by the United States Army for the disinfestation of tents, aeroplanes, buildings, etc. (But Mr. Lyttelton has announced in Parliament that the entire output of D.D.T. is being taken for military use and that, apart from a small quantity released for use in air-raid shelters, none can be released for civilian use (*The Lancet*, 485, Oct. 7, 1944).) In a reprint from *Fruit* (W. Seabrook and Sons, Chelmsford—the date of the issue of this journal containing this article is not given) it is claimed that in a field trial of 'DeDeTane' against the apple blossom weevil, a "very large reduction of infestation was secured". It is concluded, however, that much more work is required before the efficacy of D.D.T. against this weevil can be finally assessed.

It is clear that D.D.T. will have many uses other than the control of the lice which transmit typhus. Field tests should be made on its action on such insect pests of domesticated animals as the blowfly and the lice of mammals and birds. It might even prove useful against human scabies and the scab mites of animals. But we must not expect too much of it. Local factors in the environment will always affect the action of even the best insecticide. It is one thing, for example, to kill 100 per cent of house-flies or mosquito larvæ with D.D.T. or any other substance in the laboratory, and quite another to kill these quickly on a large scale in a tropical area where they are causing the deaths or illnesses of large numbers of human beings; or to do the same thing among populations whose normal habits, or disorganization during disaster, stultify the best of sanitary plans; or to apply such a remedy to large herds and flocks of domesticated animals or to extensive crops in the spacious areas of America or Australia. All remedies of this nature are subject to this kind of limitation. We are fortunate, indeed, in having, while the War lasts, opportunities for the control of both the experimental man or animal and of their environment which should enable us to investigate these aspects of the problem more thoroughly than we could investigate them in times of peace. In this respect, our partial and, we hope, temporary, loss of freedom is a help rather than a hindrance to progress.

G. LAPAGE.

# OBITUARIES

## Mr. H. P. Marks

HENRY PERCY MARKS, a member of the scientific staff of the Medical Research Council at the National Institute for Medical Research, died on September 13 after a short illness. After serving in the Navy in the War of 1914–18, Marks joined the Medical Research Council as an attached worker at Hampstead in 1922, and was appointed a member of the staff in 1927. His work at Hampstead was mainly concerned with insulin and carbohydrate metabolism although, in collaboration with others at the Institute, he also carried out interesting work on the mechanism of action of calciferol. More recently, Marks had become interested in the influence of the pituitary gland on carbohydrate metabolism and had published a number of papers on this aspect of the subject. For the two years immediately preceding his death he had been assisting in research work of national importance in connexion with the War, and had undertaken the arduous duties involved with the enthusiasm of a man many years younger. His untimely death will be mourned by his many colleagues and friends at Hampstead and elsewhere.

Marks's most important work was concerned with the standardization of insulin and more recently with the standardization of potamine zinc insulin. He visited both Copenhagen and Toronto in this con-

nexion, and was in part responsible for the biological assays which finally fixed the activity of the international standard preparations. As the result of his work on the standardization of insulin, Marks became interested in statistical analysis in relation to biological assay, and made some important contributions to this aspect of the subject. He was also a microchemist of some standing and had visited Graz in 1925 to attend the special course in this subject which was held there.

Personally Marks was rather shy and was not so well known among his scientific colleagues as might otherwise have been the case. But those who came into contact with him at Hampstead and elsewhere were always attracted by his charm of manner, and it is no exaggeration to say that he never failed to be on good terms with all his many colleagues. The early death of 'H. P.' will leave a gap which will be difficult to fill.

---

WE regret to announce the following deaths:

Dr. Alexis Carrel, known for his medical researches chiefly at the Rockefeller Institute of Medical Research, New York, aged seventy-one.

Prof. J. H. Priestley, professor of botany in the University of Leeds, on October 31, aged sixty-one.

Dr. D. S. Raitt, naturalist at the Marine Laboratory (Aberdeen) of the Scottish Home Department, on October 4.

# NEWS and VIEWS

## Royal Society: Medal Awards

THE following awards of Royal Society Medals for 1944 are announced:

Copley Medal to Sir Geoffrey Taylor, Yarrow research professor of the Royal Society, in recognition of his many contributions to aerodynamics, hydrodynamics, and the structure of metals, which have had a profound influence on the advance of physical science and its applications.

Rumford Medal to Dr. H. R. Ricardo, in recognition of his important contributions to research on the internal combustion engine, which have greatly influenced the development of the various types.

Davy Medal to Sir Robert Robertson, lately Government Chemist, in recognition of his researches on explosives, analytical methods, the internal structure of the diamond, and infra-red absorption spectra.

Darwin Medal to Prof. J. Stanley Gardiner, lately professor of zoology and comparative zoology in the University of Cambridge, in recognition of his work on coral reefs and on the organisms associated with such habitats.

Hughes Medal to Prof. G. I. Finch, professor of applied physical chemistry at the Imperial College of Science and Technology, in recognition of his fundamental contributions to the study of the structure and properties of surfaces, and for his important work on the electrical ignition of gases.

## Nobel Prize for Physiology and Medicine for 1943: Profs. H. Dam and E. A. Doisy

IT is announced that the Nobel Prize in Medicine for 1943 has been awarded jointly to Prof. Henrik Dam and Prof. E. A. Doisy for work on vitamin K. Looking back, we may recall that it is now fifteen years since the first Nobel Prize given for research on vitamins was shared by Sir Frederick Gowland Hopkins and Prof. C. Eijkman, as a tribute to their pioneer observations in this field of science. Prof. Eijkman had been concerned specifically with one vitamin factor, namely, vitamin $B_1$; and since then other Nobel Prizes have been awarded at various times for researches on vitamins A, C and certain components of the B complex. It is fitting that the latest prize should mark the completion of an important chapter in nutritional knowledge, namely, that concerned with vitamin K, for it is one of the vitamins, still relatively few, which have so far been proved to have important clinical uses.

It was in 1929 that Dam, working at Copenhagen, recorded hæmorrhages which occurred in chicks raised on synthetic diets poor in certain fat-soluble vitamins. In 1934 Dam and Schønheyder concluded that this disorder was due to deficiency of some new vitamin which they not inappropriately called vitamin K ("Koagulations Vitamin"). Soon afterwards they published their fundamental finding regarding the mode of action of vitamin K, namely, that it is concerned in maintaining the normal value of the prothrombin in the blood. In the course of the next year or so, several groups of workers, including Dam, demonstrated the clinical usefulness of vitamin K. It finds its application in two main directions, namely, in preventing the hæmorrhagic disease of new-born babies, and in controlling hæmorrhages after the surgical treatment of obstructive jaundice, a condition which had often proved fatal in the past. The routine method commonly used for assessing the effectiveness of vitamin K therapy, or detecting the presence of a deficiency, is based on Dam's work, namely, a determination of the level of prothrombin in the blood. Dam, who published his earlier investigations from Copenhagen, has been living in the United States of America since 1940.

The two most important forms of vitamin K occurring naturally are those known as vitamins $K_1$ and $K_2$. Like all vitamin-K active substances, they are both naphthoquinone derivatives, and both have been synthesized in recent years. Numerous active synthetic analogues are also known, and now largely replace natural $K_1$ or $K_2$ in treatment. The isolation of pure vitamin $K_1$ was reported in 1939 by Dam in collaboration with Prof. Karrer and their several co-workers; and almost simultaneously Doisy and his colleagues of the University of St. Louis isolated $K_2$. In the very same year three laboratories independently achieved the synthesis of vitamin $K_1$, namely those of Doisy, of Almquist and of Fieser. The demonstration of the vitamin activity of the relatively simple compound, 2-methyl-1,4-naphthoquinone, which can be regarded as the prototype of the K vitamins, was due to Ansbacher and Fernholz. In the following year Doisy with his collaborators crowned their chemical studies of the K group by elucidating the structure of vitamin $K_2$.

## Chair of Natural Philosophy at St. Andrews: Prof. H. Stanley Allen, F.R.S.

PROF. H. STANLEY ALLEN has retired from the chair of natural philosophy in the University of St. Andrews. His life in St. Andrews has been one of quiet painstaking work characterized by thoroughness in everything he undertook. His highest quality was a constant striving for the clearest, the best, way in which he could present a point. A simple example is his treatment of entropy. He has stated that in his opinion it is necessary that the beginner in a scientific subject should be given at the outset some familiar mental picture. He then points out that momentum is a vector quantity depending on the first power of the velocity, and remarks that therefore it is not likely to be a suitable analogy for entropy. It has to be remembered that Kelvin's definition of entropy makes it vary directly with the heat and inversely with the temperature. He then points out that on the basis of the kinetic theory of gases, not only the square of the velocity is involved, but also the time taken by one molecule to pass over the space in the near neighbourhood of any other. He finally shows that Callendar's identification of the energy with the form $\frac{1}{2}QV^2$ gives agreement. Prof. Allen has spent twenty years of his life in St. Andrews, and the sympathy of everyone who knows him will go out to him in his recent great loss through the death of his wife. All will entertain the hope that the greater freedom from routine labour consequent on his retirement may enable him to devote more time directly to the service of the science in which he takes his delight.

## Prof. J. T. Randall

DR. J. T. RANDALL has been appointed to the chair of natural philosophy in the United College, St. Andrews, in succession to Prof. H. Stanley Allen. Dr. Randall was educated at the Victoria University of Manchester under Prof. W. L. Bragg, and before joining the staff of the Research Laboratories of the General Electric Company, Ltd., Wembley, carried out research work on the scattering powers of atoms for X-rays. In 1937 he was elected a Royal Society Warren research fellow, and joined Prof. M. L. E. Oliphant in the University of Birmingham, where an intensive study of the mechanism of luminescence in solids was carried out. Publication of much of this work has been delayed for security reasons. At the outbreak of war Dr. Randall turned his attention to problems associated with radiolocation, and succeeded with Dr. H. A. H. Boot in introducing a new type of apparatus which has resulted in the saving of many lives at sea. For this work Dr. Randall and Dr. Boot were recently awarded the Thomas Gray Memorial Prize of the Royal Society of Arts. Since 1943 Dr. Randall has been a temporary lecturer in the Cavendish Laboratory, Cambridge.

## Prof. William Wilson, F.R.S.

PROF. WILLIAM WILSON, who has recently retired from the Hildred Carlile chair of physics at Bedford College, University of London, spent his student days at the Universities of London and Leipzig, and he found much to admire in the freedom of the German university system of those days and in the men who sustained it. In his early years as a physicist, he carried out much pioneer experimental work on photo-electric emission and developed a quantum theory of thermionic emission, which was published in 1912. By 1915 he had discovered the qu relation $\int p.dq = n.h$, and by introducing quantum numbers, he found an expression 1 eccentricities of the elliptic orbits of electrons he opened up a large field of progress in the of atomic structure. In 1921 he introduced th cept of generalized momentum into the theory electromagnetic field, and has since become interested in Kaluza's five-dimensional theo relativity. He was elected a fellow of the Society in 1923.

It is only possible to mention a few of Prof. W many contributions to physics; he is more fa than many scientific men with the work of phy and mathematicians of the past, and his own has in consequence a rare maturity and under ing. He thinks in an original way about a fundamental principles of physics. Beside writings in scientific journals, he completed i the third volume of a work on "Theoretical Ph which is the culmination of his lectures to adv students. It is a unifying account of many a of the subject and has great elegance of style. Wilson has always delighted to share his kno and wisdom with others and this makes him a teacher. Besides his o ..cial pupils, many colleagues and fellow workers have sough obtained help and instruction from him. H served the University of London in many capa including that of senator, member of the Ex Council and chairman of the Board of Stud Physics.

## Structure of the Kiogar Mountains

DR. E. B. BAILEY, director of the Geological S of Great Britain, gave a Friday discourse on ember 3 at the Royal Institution on "Mou that have Travelled Over Volcanoes". Many m tain chains present a complexity of internal str which recalls, with great magnification, that o ice piled sheet upon sheet by a tempest of yest In 1893 it was realized by geologists studyin Alps that a far-travelled thrust-sheet may oft distinguished by the foreign characteristics constituent geological formations, just as clearl far-travelled man by the foreign characterist his face and dress. The Kiogar mountains c borders of Tibet and India illustrate this phenon to perfection. The rock formations makin summits have very special characters spok collectively as Tibetan. The underlying form making the lower slopes are shown by their to be of the same geological age as the Ti formations overhead; but they have much familiar characters spoken of collectively as alayan. Between the Tibetan and the Hima developments lies a thick separating complex of igneous rocks. Some of these igneous rocl submarine lavas, following in normal succession the underlying Himalayan sediments. Some, ever, exhibit intrusive relations and penetrat overlying Tibetan sediments. The conclusi reached that in the days before the upheaval of local sea bottom to give the Himalayan moun an invading thrust-sheet penetrated the area the north. On its way it passed over a gro submarine volcanoes, which, driven undergr maintained a guerilla attack by injection of m material from below. Wear and tear due to drawal of over-run, overloaded mobile sedi added to the general confusion.

## Problems of the Gas Industry

ON October 24 Mr. A. E. Sylvester addressed the Fuel Luncheon Club on some immediate problems of the gas industry in Great Britain. The speaker, as managing director of the Gas Light and Coke Co., London, spoke on administrative rather than technical problems. He appealed for freedom of choice for the consumer of fuels, while recognizing the need for some sort of control to see that prices are reasonably related to cost of supply taking into account all the circumstances. The gas industry includes far too many small units, which, though possibly manufacturing gas satisfactorily, are unable to maintain the technical staffs adequate to give the service to consumers which present-day conditions require. The aggregation of the industry into larger groups would provide openings for more specialist technicians, while a national pension scheme would favour a freedom of movement which would be beneficial both to themselves and to an industry national in scope. Mr. Sylvester pleaded for sales tariffs which deal justly as between one type of consumer and another. It is sound policy to relate changes to cost as closely as circumstances permit, otherwise one article has to subsidize another. When gas is supplied to a factory, the charge must cover not only manufacture but also capital costs up to the works, and little more. For domestic fuel the charge must go further, covering the heavy costs of services to the consumer. The resultant charges must differ, otherwise justice is not done as between consumers. It was emphasized that gas is a refined fuel and is used because of the service it gives; this emphasis implying the necessity for a high standard of service throughout the country.

## A Study of Reason

PROF. H. J. PATON, in his lecture to the British Academy entitled "Can Reason be Practical?" (London: Oxford University Press, 1944. 4*s*. net), defends against recent attacks the view that moral principles are rules of reason. Some have maintained that moral judgments are merely the expression of private emotions or merely the result of pressure of the social environment, and that the attempt to justify them is 'rationalization' in the bad sense. Against these critics he argues that if they would only apply their theories to their own judgments they would see their absurdity. Those who oppose instinct or intuition to reason are making a false antithesis. The infant sucks by instinct, but ought to realize later that it was the most reasonable thing to do in the circumstances. Prof. Paton develops the positive side of his argument from the starting point that human conduct should at least be intelligent, that is to say, consistent and orderly, so that means are adapted to ends and conflicting impulses subordinated. The principles of practical reason are the result of taking this notion of order and consistency as far as it will go and generalizing as completely as possible. The rest of Prof. Paton's exposition is on Kantian lines, but with some useful clarification and, perhaps, some modification in the direction of what Kant ought to have said.

## Collaboration with French Men of Science

THE executive committee of the Association of Scientific Workers has sent a message of greeting to French men of science who have taken part in the Resistance Movement in France. "It looks forward to close collaboration between the scientific workers of both our countries for the progress of our common aims: the development of science and its use to advance the living and cultural standards of all peoples". The Association des Travailleurs Scientifiques, formed from the Resistance Movement a few days after the liberation of France, has acknowledged this greeting conveyed through Prof. Joliot-Curie. "In its refusal to accept the defeat of France as final and to submit to the subsequent German domination, the Resistance movement has, since 1940, been animated by that same spirit which inspired the entire British nation when it decided to continue the struggle. This community of ideas concerning the conduct of the war must continue in the maintenance of peace. The great contribution made by science to the national defence can be continued in the economic and social spheres of the peace-time world organization of to-morrow."

## Announcements

SIR HAROLD HARTLEY will deliver the Lavoisier Bicentenary Lecture of the Royal Society on November 16, at 4.30 p.m.

THE Club for Research on Ageing (c/o Department of Zoology and Comparative Anatomy, University, Oxford) has received from Lord Nuffield a donation of £3,000, which will enable Dr. V. Korenchevsky to continue his gerontological investigations for a period of three years. Clinical trials of the effects of vitamins on aged persons at the Tooting Bec Hospital will be finished at the end of the year. These were rendered possible during the last two years by substantial grants from Lord Nuffield and the Nuffield Foundation. The Club expresses its heartfelt thanks for these benefactions and is also very much indebted to the London County Council for most valuable co-operation.

THE Trustees of the Miners' Welfare National Scholarship Scheme invite applications for a limited number of university scholarships and exhibitions. Candidates must be either workers in or about coal mines in Great Britain, or sons or daughters of such workers, and normally should not be less than seventeen years of age on January 25. Forms of application and full particulars may be obtained from the Secretary, Miners' Welfare National Scholarship Scheme, Ashley Court, Ashtead, Surrey. Applicants for forms must state whether they apply as workers in or about mines or as children of such workers; those who come within both categories should apply as workers. Completed applications must be received by January 25.

THE Council of the Institution of Civil Engineers has set up a special War Service Committee to deal with the cases of prospective candidates for election whose engineering training has been interrupted by the War, with a view to these candidates being advised in regard to the periods of practical training and/or engineering experience and the examination qualifications they will be required to obtain before the Council will consider them qualified for election to corporate membership of the Institution. Intending candidates for election who are serving in H.M. Forces, or who have been directed into work of national service, and who were less than thirty-one years of age on November 1, should apply to the secretary for particulars.

## Crystal Structure of Coronene

THE structure of the coronene molecule, $C_{24}H_{12}$, is of particular interest in view of its peculiarly high symmetry (Fig. 1). With regard to electron distribution and bond-lengths, the structure should be somewhat intermediate between benzene and graphite. The optical and magnetic anisotropies of the molecule should also be of interest, and as a first stage in the accurate study of all these properties it is necessary to make a precise determination of the crystal structure.

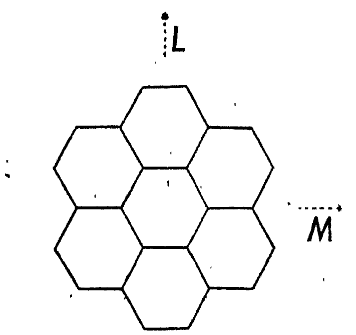

FIG. 1.

Some difficulty was experienced in growing good single crystals of the substance, but suitable specimens were finally obtained from a solution in tetrahydronaphthalene. The lath- or needle-shaped monoclinic crystals were greatly elongated along the $b$-axis, and in the best specimens the (001), (100), (10$\bar{1}$) and (20$\bar{1}$) faces were developed, the (001) usually being the most prominent. X-ray examination gave the unit cell dimensions as $a = 16{\cdot}10$ A., $b = 4{\cdot}695$ A., $c = 10{\cdot}15$ A., $\beta = 110{\cdot}8°$. The $(h0l)$ reflexions are absent when $h$ is odd, and the $(0k0)$ when $k$ is odd. The space group is therefore $C^5_{2h}$ $(P2_1/a)$. There are two centrosymmetrical molecules of $C_{24}H_{12}$ in the unit cell. (Density, measured 1·377, calc. 1·387.)

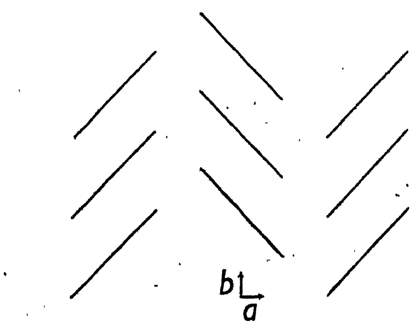

FIG. 2.

The crystal habit and especially the very short $b$ axis are similar to those of the phthalocyanines[1], and this suggested that these large flat molecules might be similarly arranged in the crystal. Detailed analysis has now shown this to be the case. The plane of the coronene molecule is inclined at approximately 45° to the $b$ crystal axis, an end view of the arrangement being roughly as shown in Fig. 2. The perpendicular distance between the molecular planes is between 3·3 and 3·4 A., just a little less than the interplanar spacing in graphite (3·41 A.).

The orientation of the coronene molecules in the crystal can be stated more precisely with reference to the molecular axes $L$ and $M$ (Fig. 1) and their normal, $N$. If $\chi_L, \psi_L, \omega_L$; $\chi_M, \psi_M, \omega_M$; and $\chi_N, \psi_N, \omega_N$, are the angles which these molecular axes make with the $a$ and $b$ crystal axes and their perpendicular, then we find

$$\begin{array}{lll} \chi_L = 85{\cdot}0° & \chi_M = 45{\cdot}3° & \chi_N = 134{\cdot}9° \\ \psi_L = 85{\cdot}1° & \psi_M = 45{\cdot}5° & \psi_N = 44{\cdot}9° \\ \omega_L = 7{\cdot}0° & \omega_M = 97{\cdot}0° & \omega_N = 89{\cdot}9° \end{array}$$

The figures are probably accurate to within 1–2°.

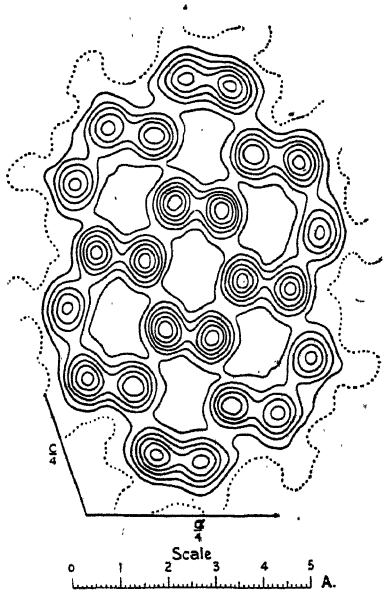

FIG. 3.

The structure is such that it is possible to compute an accurate two-dimensional projection of the electron density distribution on the (010) plane (that is, along the direction of the $b$ crystal axis) by the method of double Fourier series. The result of this calculation is shown in Fig. 3, where each line represents a density increment of approximately one electron per A.$^2$ (the one-electron line is dotted). It will be noted that every carbon atom in the molecule is very clearly resolved, and with further refinement of the measurements and calculations it should be possible to make very accurate determinations of the interatomic distances. When allowance is made for the 45° inclination of the molecular plane to the plane of the projection (010), it is found that the hexagons are regular, and already there are indications that the average C—C distance is slightly greater than the accepted value for benzene (1·39 A.). This distance is probably nearer to the graphite value of 1·42 A., but more accurate measurements and the inclusion of higher order terms are necessary before this can be definitely established. The Fourier series used for the calculation of Fig. 3 contained about eighty terms.

We are indebted to Mr. E. J. Bowen and to Messrs. Imperial Chemical Industries, Ltd., for specimens of the hydrocarbon coronene.

## Crystal Structure of β-Aluminium-Magnesium Alloy

A PIECE of β-aluminium-magnesium alloy of irregular shape, when examined by the Laue method, showed all the characteristics of the Laue symmetry $m3m = O_h$, which proves conclusively that β Al-Mg is cubic and not hexagonal as assumed by K. Riederer[1]. By means of rotation photograms the length of the edge of the unit cube was determined to be $a = 28 \cdot 13$ A. and the period of identity along a face diagonal $d = 19 \cdot 93$ A., showing that the space-lattice is face-centred. Weissenberg patterns around [100] and [110] showed that the characteristic space-group of β Al-Mg is $Fd3m = O_h^7$.

The unit cube of β Al-Mg is consequently the largest unit cell hitherto met with with alloys. With $19 \cdot 04$ A.$^3$ as volume per atom, the number of atoms per unit cube is found to be 1172, and is thus comparable with the numbers of atoms in crystals of complicated organic compounds.

## Pulsation and White Dwarfs

THE pulsation phenomenon has so far been observed only in 'super-giant' stars. However, there seems to be no theoretical reason why the phenomenon should not occur in denser stars and even in white dwarfs which are composed of *degenerate* matter. It is interesting to recall that according to current views a nova outburst is associated with a sudden collapse of the star, which after the disturbance settles down as a white dwarf. It is very likely that after such a cataclysmic disturbance the star would be left pulsating. Even if the physical conditions be not favourable for the maintenance of pulsation, yet the pulsation once started should last for a period comparable to $10^3$ years. For a white dwarf the period of pulsation corresponding to the fundamental mode is easily estimated. Assuming the 'homogeneous model', the period $P$ is given by

$$P = \left\{ \frac{9h^3}{16\pi\, m^{3/2}\, H^{5/2}\, G^2} \right\} \frac{1}{\mu^{5/2} M} \sim 10 \frac{\odot}{M} \text{ sec.},$$

where $M$ is the mass of the white dwarf, $h$ is Planck's constant, $m$ the electron mass, $H$ the proton mass, $G$ the gravitational constant, $\mu$ the mean molecular weight and $\odot$ the solar mass. In deriving the expression for the period, the effect of relativistic mechanics has been ignored. For the Stoner–Chandrasekhar critical mass the period tends to zero. The pulsation-period for a white dwarf is too small to be directly observable, and therefore the existence of pulsation in white dwarfs has to be looked for through its secondary effects.

## Thermogenic Properties of High-Frequency Currents

IN view of the interest now being taken in high-frequency heating, as a logical development of medical diathermy, successful experiments have been made in the rapid production of crustless bread, cakes and light pastries. This technique is particularly suitable for the last two named purposes. The power used was 650 watts, and the frequency $50 \times 10^6$ c.p.s. Owing to the War, further developments have not been possible.

It may be mentioned that successful experiments were made also in heating through rapidly, and in promoting the plastic flow of, kaolin ('Antiphlogistine') poultices. Our experiments indicated that this preparation is of a polar nature. It has a loss factor of about $0 \cdot 118$. The dielectric constant is also of high value, but this has yet to be determined.

If placed in a suitable non-metallic container, short-wave diathermy equipment may be used as a source of high-frequency current for this and many other applications of diathermy technique to medical preparations which require heating. This offers the advantage of uniform and rapid heating throughout, with a considerable saving in time.

## Tsetse Hybrids

IN 1936 I attempted to cross various species of tsetse (*Glossina*) with the idea that, should they hybridize readily, and should the resultant hybrids prove sterile, this might be tried as a measure of control. Corson had already, in 1932, obtained three offspring from crosses between male *G. swynnertoni* and female *G. morsitans*; he suggested, however, that these might not be true hybrids, but the result of parthenogenesis (see further details in the accompanying communication by Mr. F. L. Vanderplank). I obtained a number of offspring from this and other crosses, but as a slight doubt arose as to whether they were authentic hybrids, the results were never published.

The doubts arose because the females used had not come from pupæ kept isolated in single tubes, but from collections of pupæ from which the emergent imagines were cleared three times a day except during the week-end, when forty-four hours elapsed between the last clearing of the jars at midday on Saturday and their first clearance on Monday at 8 a.m. Females were therefore left for varying periods up to forty-four hours in contact with freshly emerged males of their own species before isolation for crossing. Though the work of Mellanby[1] rendered it very unlikely that females in such circumstances could become inseminated by their own species, a doubt did remain. Since then I have kept females similarly obtained without subsequent access to males, and none of them has shown any signs of fertility though they lived twenty-one days or more, sufficient to allow them to produce at least one larva; eighty females were dissected and none was found to have been inseminated. Mr. Vanderplank and I have both found that the external characters of *swynnertoni* are completely dominant in the offspring of these crosses, and the production of a *swynnertoni*-like fly by a *morsitans* female is conclusive evidence that a true hybrid has been obtained; recent exam-

ination of the genitalia of the male 'hybrids' has shown them to differ from those of both parents. Since also recent experiments by my colleague, Mr. F. L. Vanderplank (see accompanying communication), using females obtained from pupæ kept singly in tubes, have resulted in the production of similar offspring, an account of my earlier results is perhaps desirable.

Of twenty-eight female *G. swynnertoni*, paired with male *G. morsitans* and surviving twenty-one days or more, three (10·7 per cent) produced seven pupæ (2, 4 and 1 respectively) of which one was accidentally destroyed, one failed to emerge, and five produced imagines—2 ♂♂ and 2 ♀♀ and one the sex of which was not determined before it escaped. All these resembled the female parent in appearance and so might not have been true hybrids. But of forty female *G. morsitans* paired with male *G. swynnertoni*, three (7·5 per cent) produced five pupæ (2, 1 and 2 respectively), all of which produced imagines (2 ♂♂ and 3 ♀♀). This time all the offspring resembled the male parent and so must have been hybrids; as already remarked, the external characters of *swynnertoni* are dominant. I propose for the sake of brevity to call the results of the ♂ *swynnertoni* × ♀ *morsitans* cross '*swynnertans*' and of the reverse cross '*morsitoni*'.

Using the hybrids described above, two '*morsitoni*' females were crossed with male *swynnertoni* and *morsitans* respectively, and each produced pupæ, four apiece. Again, two '*swynnertans*' females crossed with ♂ *swynnertoni* produced five pupæ (3 and 2 respectively), but a third, crossed with a ♂ '*morsitoni*', failed to produce. Of these thirteen pupæ seven produced imagines, of which five were females, one was a male and one escaped before its sex could be determined. Of the five females two were crossed with pure-bred ♂ *swynnertoni* and *morsitans* respectively, two with '*morsitoni*' ♂♂, and the fifth with the one second generation male hybrid. None produced any offspring.

A series of controls (*morsitans* × *morsitans* and *swynnertoni* × *swynnertoni*) was kept simultaneously and under similar conditions (in single tubes, the pair generally remaining together until the male died). These continued to a fourth generation, which was still producing pupæ when the observations ceased.

My observations, the results of which are summarized above, and a fuller account of which is in preparation, seemed to show that the inter-specific couplings were undertaken with greater reluctance than the intra-specific ones, so that this, combined with the very scanty production of hybrids, and the fertility of the first generation of the hybrids, led to an abandonment of this line of investigation as a possible means for the control of tsetse, which seemed to me to depend on ready cross-mating and on free production of sterile hybrids. The more recent work of Mr. Vanderplank has, however, led to a reconsideration of the project, for he has shown that the two species mate freely, and are also likely to do so under natural conditions; his results have also suggested that I was lucky in the reproduction by my hybrids, for he has not, so far, obtained any pupæ from such hybrids as he has worked with. He has further pointed out that the poor production of first generation hybrids is itself a very possible means of control since it means that, where the introduced species can be released in numbers greatly exceeding those of the indigenous species, a large number of the indigenous females will be rendered sterile.

Briefly, the proposed measure of control involves the introduction of large numbers of pupæ of the alien species into country in which the infestation by the indigenous species is naturally low or artificially reduced. The hope is that the indigenous species will be sterilized and exterminated; and that thereafter, when introductions of the alien species are discontinued, it also will eventually die out, because the environment is not of a type suited to its permanent survival.

Other experiments were carried out with the above two species and *G. pallidipes*, *G. palpalis* and *G. austeni*, in various combinations, but though in each case evidence of the insemination of females by the alien males was obtained, no pupæ were produced; the numbers used, however, were too small to allow the possibility of success in these further crosses to be completely denied.

## Hybridization between Glossina Species and Suggested New Method for Control of Certain Species of Tsetse

Corson[1] and Potts[2] record crossing *Glossina swynnertoni* Aust. with *G. morsitans* Westwood. Corson crossed twelve female *G. morsitans* with male *G. swynnertoni*, of which only two females produced a total of three pupæ. All his females lived long enough for reproduction to take place. He records the offspring, all females, as being identical with pure-bred *G. morsitans*, and suggested parthenogenesis. Potts crossed both male *G. morsitans* with female *G. swynnertoni* and male *G. swynnertoni* with female *G. morsitans* (see accompanying communication by Mr. W. H. Potts).

I have recently re-investigated the hybridization of these species to test whether this might not result in sufficient interference with breeding to allow it to be used as a control measure.

All the females used in the experiments were obtained from pupæ kept singly in tubes or were isolated immediately on emergence from collections of pupæ; the females were kept individually in tubes and carefully fed; at death each female was dissected. The results are summarized in the accompanying table.

The *swynnertoni* females emerged from pupæ collected in the Shinyanga area where *G. pallidipes* were also present, but not *G. morsitans*, and the *morsitans* females were from pupæ collected in a pure *morsitans* belt at Kondoa Irangi.

The table shows: (1) that insemination of the females in inter-specific crosses took place as readily as in the intra-specific when no choice was offered, and (2) that inter-specific crosses were far less successful in producing pupæ in spite of the fact that the average life of these females was not appreciably different from that of the intra-specific controls.

*G. pallidipes* males and females were very reluctant to mate with either *G. morsitans* or *G. swynnertoni* and only could be mated in special circumstances. No successful mating took place between female *G. pallidipes* and the other species; one male *G.*

| Nature of cross ♂ | Percentage of ♀♀ inseminated | Percentage of inseminated ♀♀ living over 21 days which produced pupæ | No. of pupæ produced per inseminated ♀ living over 21 days | Average life of ♀♀ in days |
|---|---|---|---|---|
| *G. morsitans*♂♂ Expt. X *G. swynnertoni*♀♀ | 92% (37) | 10% (31) | 0·1 (3) | 70 (40) |
| *G. swynnertoni*♂♂ Control X *G. swynnertoni*♀♀ | 80% (12) | 100% (7) | 2·4 (17) | 61 (12) |
| *G. swynnertoni*♂♂ Expt. X *G. morsitans*♀♀ | 96% (45) | 24% (33) | 0·4 (13) | 68 (47) |
| *G. morsitans*♂♂ Control *G. morsitans*♀♀ | 76% (19) | 100% (10) | 4·0 (40) | 75 (19) |

N.B.—The numbers in brackets give the totals on which the percentages or averages are based; these are not the same throughout the table, as some females, counted as inseminated on the evidence of dissection, did not live long enough to produce pupæ, and also some of the females which were used to give the average life were not dissected to show insemination.

*pallidipes* mated with but failed to inseminate a female *G. morsitans*, and four male *G. pallidipes* mated with and inseminated four female *G. swynnertoni*, none of which had offspring.

The numbers of tsetse in these experiments were limited by the amount of work involved in their maintenance; to feed these adequately took six African assistants full time daily, including Sundays. The longevities of the various batches are not significantly different from each other by Student's *t* test, nor are the percentages of each group, inseminated or not, significantly different by the $\chi_c$ test, but the number of inter-specifically mated females that produced and numbers of pupæ produced by them are significantly smaller than their controls ($\chi_c$ test).

Other experiments, in which equal numbers of male and female *G. swynnertoni*, *G. morsitans* and *G. pallidipes* were mixed in a cage 30 × 30 × 30 cm., showed that mating between *G. swynnertoni* and *G. morsitans* not only occurred as readily as between the opposite sexes of the same species when no choice was offered, but also took place at random, but *G. pallidipes* did not mate with either, nor did any of the male *G. swynnertoni* or *G. morsitans* mate with *G. pallidipes*. A field experiment releasing 600 *G. morsitans* from pupæ in a *G. swynnertoni* area by Dr. C. H. N. Jackson, of this Department, showed similar results to those obtained in the laboratory. The recaptured females were kept alive, and the male genitalia of the offspring were examined.

The male hybrids have distinct genitalia and show affinities to the female parent. All the hybrids were similar to *G. swynnertoni* in external markings, contrary to Corson's observations. Both types of male and female hybrids have been crossed with each other and with pure-bred male and female *G. swynnertoni* and *G. morsitans*. The male hybrids inseminate the females, both hybrid and pure-bred, but none has reproduced or showed signs of successful fertilization. So far attempts to cross female hybrids with pure-bred males of both species have failed. Though the hybrid females were laboratory-produced flies, they lived even longer than their female parents, averaging 106·0 days.

Experiments have also shown that a few hours after a female is inseminated she is no longer attractive to males and will not permit further coitus.

Work is being continued with other species and pupæ of the same species collected in other areas. A field-scale experiment to exterminate *G. swynnertoni* by releasing large numbers of *G. morsitans* has been begun in an isolated block of scanty *G. swynnertoni* country. It appears likely that *G. morsitans* would be unable to survive permanently in the area.

It is hoped to publish full details of this work shortly elsewhere. I am indebted to Mr. W. H. Potts and Dr. C. H. N. Jackson for their help and co-operation in this work, and to Mr. S. Napier Bax, the acting director, for permission to publish this.

## Fertilization of *A. maculipennis* var. *labranchiae* in the Laboratory

*A. maculipennis* var. *labranchiæ* is reported to swarm readily in a small cage (1 m. high and 50 cm. wide) if a blue light of intensity about 3 f.c. at a distance of 30 cm. is placed on top of the cage[1]. No record is known of laboratory mating of this variety without these experimental conditions.

*A. maculipennis* var. *labranchiæ* was reared in the laboratory from eggs, and the adults allowed to emerge in a cage of wire mesh, dimensions 47 cm. × 47 cm. × 60 cm. The cage was situated approximately 5 metres from the window of the laboratory, and the end nearest the window covered with a damp cloth. Under these conditions *labranchiæ* fed readily at any hour of the day on an arm introduced into the cage. After a period of ten days, viable eggs were laid in bowls of tap-water in the cage, although no artificial light of any kind was provided. Swarming was not observed.

The experiments are continuing.

## Relation of 'Folic Acid' to the Nutritional Requirements of the Mosquito Larva

IN our investigations on the nutritional requirements of the larva of *Aedes ægypti*, our procedure has been based on the methods employed by Trager[1]. Various modifications have been introduced which make for increased accuracy of observation and clearer interpretation of the results. Thus larger groups of larvæ were used, each larva being placed in a separate tube and its stage of development noted every morning and evening. All liquid media were sterilized by Seitz filtration and the contents of the tubes tested for sterility at the conclusion of each experiment.

In media capable of supporting growth, we have constantly noted that the length of time taken to reach the second, third and fourth larval instars, as well as the pupa, depends directly on the degree of adequacy of the medium. On this also depends the proportion of larvæ surviving. By suitable choice of media it is possible to interrupt larval development

at any stage, the larvæ dying in that stage, often only after many weeks have elapsed. In the wide variety of media we have used, the time taken for the change from pupa to adult has proved to be independent of the diet. In sixty experiments involving more than a thousand pupæ, this period ranged from two to three days (mean $2 \cdot 4 \pm 0 \cdot 46$ days). Ninety-seven per cent of these pupæ emerged as adults, indicating that as a rule emergence also is unaffected by the medium.

As originally reported by Trager[1], a medium comprising autoclaved yeast and liver extract is adequate for normal growth of mosquito larvæ. We have found it possible to bring to maturity 65–95 per cent of larvæ in groups grown in a sterile medium of autoclaved brewer's yeast suspended in 0·01 *M* solution of calcium chloride. A number of simple treatments have an adverse effect on the growth-promoting properties of autoclaved yeast. Thus prolonged autoclaving, and the storage of autoclaved yeast for a long period, both lead to reduced survival of the larvæ and an extended time for the change from one stage of development to the next. With dried brewer's yeast variable results were obtained; they appeared to depend on the conditions of drying and the period of storage of the dried material. On autolysing fresh brewer's yeast it was found that neither the autolysate, nor the residue, nor a combination of both was capable of promoting the same rate of growth and survival as the whole yeast had done. The autolysate and residue could not be made equivalent to the original yeast by the addition of any one of, or of all, the following substances: thiamin, riboflavin, pyridoxin, calcium pantothenate, nicotinic and *p*-aminobenzoic acids, biotin, *i*-inositol, choline and glutathione. The desired effect could, however, be brought about by the inclusion of liver extract (Armour) in the medium.

An insoluble yeast residue was prepared by exhaustive extraction of fresh brewer's yeast with boiling water. The autoclaved residue was used in conjunction with a large number of media containing some or all of the compounds listed above. The media also contained glucose, salt mixture and yeast nucleic acid. They were adjusted to *p*H 5·8. In the absence of added thiamin, riboflavin, pyridoxin, pantothenate or nicotinic acid, little or no growth occurred. On the other hand, the addition of the following substances had no apparent effect on the growth of the larvæ: biotin, inositol, *p*-aminobenzoic acid, choline and glutathione. Microbiological assay, using *Lactobacillus casei*, revealed the presence of bound biotin in the yeast residue, and the inclusion of avidin in the medium so clearly inhibited growth as to leave little doubt that biotin is an essential growth-factor for mosquito larvæ. Choline and glutathione could not be detected in the yeast residue; it seems that these compounds are not essential nutritional factors for mosquito larvæ, as claimed by Trager[2].

In all these experiments, one especially significant fact emerged: although the media employed were capable of supporting good growth to the fourth instar, *pupation did not occur*. The active, fully grown larvæ died in the fourth instar, usually after surviving for periods up to six weeks. In many instances, too, they were incapable of completely disengaging their third instar pelts, and died with the pelts still attached. Although the chitinous portions of the head and siphon were normally pigmented, the bodies of the larvæ were entirely free from pigment. The regularity with which failure to pupate was observed under these conditions is indicated by the fact that in thirty-five experiments using insoluble yeast residue and involving a total of more than seven hundred larvæ, of which two thirds reached the fourth instar, only 1·3 per cent were transformed into pupæ. It was obvious, therefore, that at least one water-soluble, heat-labile factor was still missing from our media.

Investigations on the effect of adding various other compounds, such as vitamins, amino-acids, purine and pyrimidine bases to the above media, have brought to light only three preparations capable of bringing about pupation. They are: a concentrate of vitamin $B_c$, the chick anti-anæmia factor, prepared from liver according to the directions of O'Dell and Hogan[3]; a concentrate of the ammonium salt of folic acid of potency 5,000, kindly supplied by Prof. R. J. Williams; the 'Norite eluate factor' of Peterson[4], kindly supplied by Lederle Laboratories.

These concentrates have been found to exercise a four-fold effect: (1) they induce pupation with striking regularity; (2) they improve the rate of growth to that observed with our best media (for example, fresh brewer's yeast and liver extract); (3) they effect an increase in the size of the larvæ; (4) they produce pigmentation of the bodies of the larvæ.

These findings serve to emphasize the close relationship known to exist between these factors and to indicate their possible identity. From the work of Elvehjem and his collaborators[5] it would seem that such concentrates as these may contain vitamins $B_{10}$ and $B_{11}$ in addition to folic acid. Thus while it is probable that the active factor in our preparations is folic acid, it cannot be regarded as certain.

It is known that xanthopterin may be present in concentrates of folic acid, and Mitchell[6] has provided some evidence of a structural similarity between the molecules of xanthopterin and of folic acid. The possibility that xanthopterin is active in bringing about pupation of *Aedes* larvæ was investigated, using the pure substance synthesized by a modification of the method of Purrmann[7]. It failed to bring about pupation, or any of the other changes characteristic of folic acid.

It is interesting to consider the possible mechanism by which these nutritional factors induce pupation. A number of workers have shown that moulting and pupation are caused by one or more hormones. In some insects the corpora allata have been proved to be the source of the hormone, while in others the source is uncertain. Our examination of 'Weismann's ring', which is thought by some to represent the corpora allata in mosquito larvæ, was inconclusive when carried out on normal fourth-stage larvæ from the insectary and on larvæ from a medium in which pupation will not occur. We have, however, noted a striking difference in the large œnocytes. In the larvæ from the insectary they are large, measuring up to 44 μ, and the cytoplasm is filled with numbers of vacuoles. In fourth-stage larvæ grown in a folic acid-free medium they are small, the largest measuring only 16 μ, and vacuoles are minute or entirely absent.

It is unlikely that 'folic acid' is itself a pupation hormone. This is indicated by the fact that transference of fourth-stage larvæ from a folic acid-free medium to one containing folic acid concentrate or brewer's yeast does not cause metamorphosis, whether the larvæ are transferred immediately after reaching the fourth instar, or eleven days later. On the other

hand, similar transference of newly moulted second- or third-stage larvæ results in normal growth, pigmentation and pupation. It seems probable, therefore, that folic acid functions by stimulating the production of a pupation hormone within the growing larva; but that it is incapable of doing so in a fully grown larva.

One final observation must be recorded here. In the insectary it is most unusual to find a weak adult mosquito, that is, one which on emerging cannot rise from the water. In our experiments, however, even on the most complete media, a large proportion of the adults were weak, irrespective of sex. Under the same conditions, when grown on contaminated media, all the adults were vigorous. There is thus some further factor, the nature of which we have not yet investigated, which is responsible for the development of vigorous adult mosquitoes.

We wish to thank the commanding officer, Technical Staff, Medical Laboratory Service, South African Medical Corps, who enabled one of us (M.L.) to participate in this investigation.

## Effects of Secretions

SOME secretions of some organisms found to be inimical to some metabolic step necessary to the normal processes of some other organisms have come to be referred to as 'antibiotics'[1,2]. As has been pointed out by Lucas[3], it seems likely that it will be found profitable to regard such secretions as special cases of that great class of substances, distinguished by being physiologically active, the study of which constitutes a large branch of comparative physiology, and to consider their effects in terms of the evolution, by natural selection, of the organisms concerned. Their adverse effects on some organisms are presumably an example of these organisms not being adapted in a particular respect, comparable, in principle, with many other examples in ecology.

If this much be granted, then it would seem to become important that the nomenclature used in considering them shall be such as shall fit easily into the language of biological discussion. I suggest that 'antibiotic' is not such a word, and, further, that it contains implications contrary to what we believe to be the truth.

The word as it stands will, I think, suggest to nearly everyone 'opposed in general to the act of living'—in fact, a poison. But if my life is saved by penicillin, is the fact sufficiently reflected by calling penicillin an antibiotic in this sense? I think consideration of this difficulty, thus presented, may show that two mistakes have been made:

(1) It is not true, though it is implied, that penicillin (for example) is opposed to life in general. Few things are: one man's poison is notoriously another man's meat.

(2) It is true, though it is not stated, that because of the peculiar fact that penicillin (for example) is produced by certain organisms and adversely affects certain other organisms, it possesses the function, in Nature, not of forbidding life, but of precluding certain associations of living things, while permitting, or even encouraging, others. It acts upon a relationship.

Whether, on balance, life is increased or decreased as a result of the effects of one of these substances is likely to be almost impossible to determine. Whether more or fewer molecules are organized for life at any time than would have been without the action of the substance is a question which can scarcely be readily answered. Yet, this is just the question that the word 'antibiotic' appears to presume to answer.

Now, in medical practice, and in other branches of applied biology, the precluding of certain associations may seem to be the important thing. This one effect among many, therefore, is chosen as wanting a name. But this precluding of certain associations is not described in the word 'antibiotic'.

What we need is two words, one of which shall mean 'promoting certain associations of (perhaps named) living things', or, better 'promoting certain symbioses', and the opposite of that.

If, singling out for our own purposes one of its actions, we call a substance promoting certain such relationships a 'prosymbiotic', as I think we might, then perhaps we could call its opposite an 'antisymbiotic'. Thus penicillin could be called an antisymbiotic between *Penicillium notatum* and certain organisms which could be named as a group or individually as the context required. Penicillin could also be called a prosymbiotic between *Penicillium notatum* and certain other organisms as and when these came to be distinguished.

I make this suggestion tentatively, to direct attention to what I believe to be a serious conceptual confusion. I hope that others may improve upon it.

I think that these words can be applied in wider fields than that of bacteriology. They refer to the function of such substances, and to their origin in Nature. Of course, we may be able, for example, to take an antisymbiotic away from the organism producing it, or synthesize it, and use it in our attack on some organism adversely affected. But this artificiality does not affect the validity of the term.

## Protective Action of Potassium Iodide on Thiourea Poisoning in Rats

KENNEDY[1], in reporting the goitrogenic action of the thioureas in rats, mentioned that doses of 200 mgm. of thiourea had no toxic action. This accords with the experience of Astwood[2]. On the other hand, MacKenzie and MacKenzie[3] found thiourea to be highly toxic to adult rats. During 1943 thiourea was administered to large numbers of rats in our laboratory with only infrequent deaths. Such deaths as did take place occurred on the first day of thiourea

administration, and autopsy disclosed a condition of pulmonary œdema and pleural effusion, as described by MacKenzie and MacKenzie. From the beginning of 1944 we have, however, experienced a heavy mortality in rats receiving thiourea. Up to 66 per cent of rats have died and the remainder have recovered only after a period of severe respiratory distress. The severity of the symptoms does not seem to be proportional to the dose of thiourea administered, and in susceptible groups of rats the provision of drinking water containing 0·025 per cent of thiourea has resulted in the death of 50 per cent of the animals. Plainly the response of our rats to thiourea administration has undergone an abrupt change. The same change in response was observed in two separate strains of rats, while no variation of composition of diet or environment had been consciously introduced. We are unable to account for this change but our investigations have confirmed the reported immunity[3] of young rats, and also of adult rats which have survived the first dose of thiourea.

Recently, it has been found that treatment with potassium iodide (1·3 mgm. by subcutaneous injection for four days) prevents the acute toxicity of subsequently administered thiourea. The iodide gave the same protection in thyroidectomized animals as in intact animals, so that this protection, like the toxicity, is unrelated to thyroid activity. Potassium bromide and potassium chloride in equivalent dosage did not exert a protective action.

The acute toxicity of thiourea resulting in pulmonary œdema has not been recorded in human beings. A number of minor toxic manifestations related to capillary permeability, namely, œdema of legs and of eyelids, watering of the eyes, and skin rashes have been recorded[4] in patients receiving thiourea for treatment of thyrotoxicosis. It is at present being tested whether simultaneous administration of iodide to such patients will lessen the incidence of such manifestations.

## Graphical Representation of Growth Gradients

GROWTH gradients in animals have been represented by a method described by Huxley[1], based on growth constants, that is, the values of $\alpha$ in the allometry formula[2], $y = bx^{\alpha}$. Huxley[1] has discussed the inadequacy of his graphical method and the formal difficulties of devising a better, but no attempt seems to have been made to overcome these difficulties. It is thought that the simple mathematical considerations below constitute a solution to the formal obstacles in the way of the quantitatively accurate representation of certain types of growth gradient. The gradients referred to here are gradients in heterauxesis[3] in which the growth intensities are in the direction of the axis along which the gradient lies. Multiplicative growth in length only is discussed, but similar concepts apply to multiplicative growth in area, volume and weight.

If there is a growing axis, and in it a morphologically differentiated point of reference, $O$, and other similarly differentiated points $A$, $B$, $C$, . . ., $Y$, . . . , the lengths of the regions $OA$, $OB$, $OC$, . . . , $OY$, . . . , can be considered in two ways, namely, (1) throughout growth, as functions of the length of some standard region of the body, and (2) at any particular moment during growth, as special values of the length $OR$, where $R$ is a point of variable position in the axis, that is, $OR$ is an independent variable. Regarding the above regions in sense (1), the significant expression of the growth-rate of a morphologically differentiated region $OY$, of length $y$, relative to the standard dimension, $x$, may be given by the relative specific growth-rate, or growth potential, of $OY$, $P_{OY} = \frac{dy}{dx} \cdot \frac{x}{y}$. As defined, $P_{OY}$ may or may not remain constant during growth, so that it is not necessarily equivalent to a growth constant. Growth potential is adopted for the present purpose because it is a more general conception than growth constant, and because the mathematical inconsistencies in the additive properties of growth ratios are avoided. Regarding the regions in sense (2), when the standard dimension equals $x$, the growth potential $p_R$, *at the point* $R$ in the direction of the axis, may be defined as the limit of $P_{RS}$ as $RS$ tends to zero, where $S$ is another point of variable position in the axis. The direction of the growth potential at a point must obviously be specified.

Let $OR = z$, which, it should be emphasized, is an independent variable. Now, if growth potential is an adequate indication of growth intensity, and if the idea of growth gradients is fully justified, at any stage of growth $p_R$ should be a function of $x$ and $z$, that is,

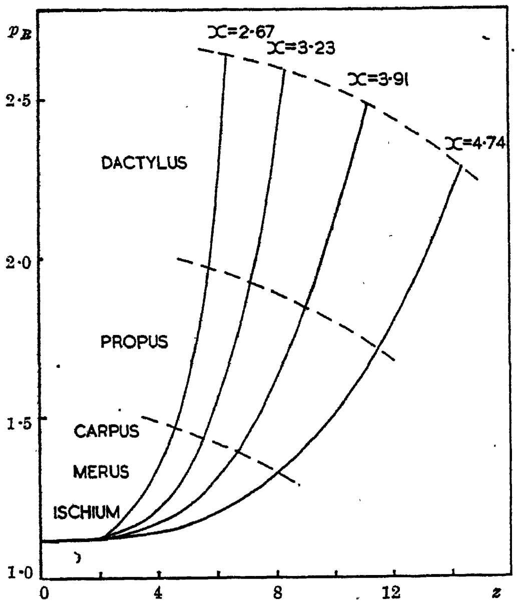
$$p_R = f(x,z). \qquad (1)$$

Furthermore, for any particular value of $x$, $p_R$ should be a *continuous* function of $z$. Equation (1) can be represented by a number of curves in one plane, and such a curve diagram will be a quantitatively accurate picture of the growth gradient. The curve for any particular value, say $k$, of $x$, may be derived as follows. It can be shown mathematically that $P_{OR}$ is equal to the arithmetic mean of the growth potentials in the direction of the axis at all points in $OR$. Combining this fact with equation (1) we have

$$[P_{OR}]_{x=k} = \frac{1}{z}\int_0^z [p_R]_{x=k}\, dz. \qquad (2)$$

Hence, if particular values of $P_{OR}$, namely, $P_{OA}$, $P_{OB}$, . . . , are known, and if the morphologically differentiated points $A$, $B$, . . . , are sufficiently numerous and suitably spaced, a graphical representation of equation (1) may be obtained graphically by means of equation (2) or a transformation of equation (2).

For the above method of analysis it is necessary to know the lengths of several successive morphological regions, adjoining end to end, for a number of different body sizes. There are very few data of this kind in the literature, but the accompanying figure is the outcome of an analysis of the data given by Tazelaar[4] for the segment lengths of the chela of the male prawn *Palæmon carcinus*, for carapace



GRADIENT OF LENGTH-GROWTH IN THE CHELA OF THE MALE *Palæmon carcinus*.

The growth potentials, $p_R$, at points have been plotted against the distance, $z$, in cm. distal to the basal end of the ischium for different carapace lengths, $x$, also in cm.

length 2·67–4·74 cm. The data were not designed for this purpose, however, and the figure should be regarded as an example of the method rather than a very accurate representation of the growth gradient. It was found convenient to employ a transformation of equation (2), namely,

$$p_R = [P_{OR}]_{x=k} + z\frac{d}{dz}[P_{OR}]_{x=k}. \qquad (3)$$

The curves of the figure correspond to values of $x$ in geometrical progression, which seems logical since growth is a multiplicative process.

It has been pointed out to me by Mr. E. D. van Rest, to whom I am much indebted for criticisms and suggestions, that there is more to the problem than this short account might suggest. For example, growth potential at a point as defined is determined partly by the length of the standard region, which may itself be subject to variations in growth potential from point to point. It is hoped to discuss this and other questions elsewhere.

## Kemp in New Zealand Romney Sheep and its Significance for Mountain Breeds

SELECTION against kemp in the Romney is a simple matter, scarcely amounting to a breeder's problem, but facts learnt from Romneys may be offered to breeders of mountain sheep that characteristically have hairy birthcoats. In Romney sheep, selection against high abundance of halo-hairs is a sufficient safeguard against kemp, and selection against halo-hairs is effective. On the backs of lambs with abundant halo-hairs (large birthcoat kemps of generation I, $G_1$), there may or may not be secondary kemp. Birthcoat kemps are shed around the third month after birth. Halo-hairs are nearly always all shed. Occasionally an odd halo-hair is of indeterminate growth. Super-sickle-fibres, whether in non-plateau or plateau arrays, sickle-fibres which are the key type in non-plateau arrays, and hairy-tip-curly-tip fibres which are the key type in plateau, vary in their shedding from all to none. The shed birthcoat fibres are succeeded by other fibres which when they are shed are later, or secondary, kemps. In non-plateau, later kemp is grown mostly in the follicles of the halo-hairs, occasionally, as we conclude, in some super-sickle-fibre follicles, scarcely ever in those of sickle-fibres. In plateau, super-sickle-fibres and hairy-tip-curly-tip fibres, as well as the very abundant halo-hairs, are readily followed by kemps, so that there is often a huge amount of secondary kemp in N-type lambs.

In non-plateau fibre type arrays the successors ($G_2$ fibres) of halo-hairs are shed freely, that is, are kemps, only when a substantial majority of the sickle-fibres with bigger sickle-ends are shed. When the shedding of sickle-fibres is less than very free, there is a certain correspondence in extent of shedding of sickle-fibres and of $G_2$ fibres. Kemp is plentiful among the successors ($G_3$), grown at seven months and later, of the shed successors ($G_2$) of halo-hairs, only when the array is one indicative of a weak pre-natal check, namely, saddle or a near approach to saddle. When the array is valley there is little $G_3$ kemp, and saddle *v.* valley is a matter of strong inheritance.

When kemp succession relations were defined in non-plateau arrays it was expected that a corresponding generalization could be made for plateau array. This is the array, typically lacking sickle-fibres, of N-type lambs, these being like hairy mountain lambs. A study (by J. M. R.) of succession on the back of eighty covered lambs has improved upon an earlier generalization. When the shedding of hairy-tip-curly-tip fibres is very free (on present data more than 45 per cent) there is much $G_2$ kemp. When there is no shedding of hairy-tip-curly-tip fibres there is little $G_2$ kemp. When the shedding of hairy-tip-curly-tip fibres is intermediate there is great diversity in the $G_2$ kemp figures. Higher abundance of hairy-tip-curly-tip fibres (on present data more than 26 per 500 fibres of the lamb's full fleece) is then accompanied by much $G_2$ kemp, lower abundance of hairy-tip-curly-tip fibres by little $G_2$ kemp. Intermediate abundance of $G_2$ kemp shows signs of being associated with very poor shedding of hairy-tip-curly-tip fibres, or with low numbers of these fibres. In plateau array abundant $G_2$ kemp is almost always followed by plentiful $G_3$ kemp. In both non-plateau and plateau arrays when $G_3$ kemp is plentiful, $G_4$ kemps have often at least started to grow before shearing at about fifteen months. The expectation that kemp succession relations in plateau would show a general similarity to those in non-plateau has been justified. In both non-plateau and plateau arrays a small number of exceptions to our generalizations have been found, but they lend themselves to explanations that seem both reasonable and instructive.

There is some evidence that abundance of secondary kemp in N-type is inherited. In breeding experiments on the genetics of N-type it has often happened, partly incidentally, partly by choice, that both parents have had much $G_2$ kemp. The large proportion of resulting lambs with much $G_2$ kemp suggests that this selection has been effective. Small attempts

to breed against $G_2$ kemp in N-type have, however, achieved little, but the rams hitherto available have not been so free from $G_2$ kemp as one would have wished. There is also an argument by analogy from the inheritance of birthcoat characters. Abundance of halo-hairs and fibre type array, as stated earlier, are strongly inherited. The freedom from chalkiness, that is, no medulla or no appreciable medulla, in the post-natal region and, besides, in the sickle-end, of all sickle-fibres in numerous Wensleydale specimens sent from England by Dr. K. M. Rudall, is manifestly inherited. These facts, and especially the last detail, suggest that the hairiness (chalkiness) of the tips of fibres of the curly-tip group in N-type is likewise genetically determined, and consequently that the abundance of secondary kemp is inherited. Bryant secured direct evidence from a Scottish Blackface flock.

Our fundamental aim is to understand the interaction of forces at work in the follicles. Our present purpose is to point to possible application of our findings in selection against later kemp in mountain sheep in which a kempy birthcoat is accepted and desired. In particular, it may prove practicable to judge very young lambs for later kempiness. Biological work on the fleece is slow, especially when breeding is involved, and we are therefore presenting this preliminary report on new facts about secondary kemp in N-type Romney lambs.

## High Fertility of Buckwheat Tetraploids obtained by Means of Colchicine Treatment

IN the summer of 1941, extensive experiments were performed on producing buckwheat tetraploids by means of colchicine treatment. In 1942 the root tips of a thousand seedlings grown from seeds of the initial experimental plants were studied cytologically. Among the seedlings verified cytologically, 250 bore the tetraploid chromosome set (32 instead of the normal 16). Tetraploids were obtained from 79 initial plants of the following nine buckwheat varieties: 'Bolshevik', 37 initial plants; 'Kharkovskaya', 10; 'Bogatyr', 6; 'BTSKA' (-Timiriasev Agricultural Academy), 6; 'Altaiskaya', 5; 'Ispanskaya serebristaya', 5; 'Kazakskaya', 5; 'Belorusskaya', 3; and 'Buriat-Mongolskaya', 2.

In the summer of 1942, the non-crossability of the buckwheat tetraploids with buckwheat diploids was confirmed, this fact being of outstanding importance for selection.

The comparative study of tetraploid plants carried on in 1942 and 1943 invariably showed a marked increase in size of seed (on the average surpassing the weight of the diploid seeds by 42–85 per cent along with general enlargement of the plants).

As is usually the case in autopolyploidy, the majority of the new buckwheat forms were marked by a pronounced decrease in fertility as compared with the diploid plants. However, our extensive initial material, hereditarily different both as regards the nine varieties and within each variety as well, made it possible to select for reproduction those plants which were marked by the largest seeds and by greatest fertility. Subsequent selection of their progeny (for some stocks four generations of tetraploids were obtained for two years) already in 1943 showed a number of autotetraploid highly fertile buckwheat stocks with large seeds.

In the progeny of the best tetraploids of the variety 'Bolshevik', we obtained on the average from double to four times more seeds than from the diploids. Thus along with the greater weight of the seeds (1·5 times heavier) this latter fact increased the crop from the tetraploid plants from three to six times as compared with the normal diploids. Alone, 'Bolshevik' had produced in 1943 more than 15 kgm. of seeds.

The main theoretical importance of the data obtained consists in the fact that buckwheat is the first case illustrating high fertility of an experimentally produced, agriculturally valuable autopolyploid form. Of practical importance is the fact that during the shortest possible period (two and a half years) highly fertile buckwheat forms with large seeds have been produced, non-crossable with the initial diploid plants.

Some data point to the assumption that owing to their vigorous growth tetraploids show a higher percentage of germinating seeds under field conditions, as compared with the diploids. They are more frost-resistant and they show more pronounced self-pollination, which is seldom noted for normal buckwheat forms.

## Lunar Coronæ

A DISPLAY of lunar coronæ was seen here in alto-cumulus cloud on October 2 between 10.30 and 11.30 p.m. At its greatest extent the red ring of the third order was visible, but those parts of the corona outside the second red ring were fragmentary. On at least one other occasion the whole corona up to the green of the second order was seen.

Some measurements were made towards the end of the observations, and these and the calculated diameters of cloud droplets are recorded in the accompanying table. The unit of angular measurement is the moon's radius.

| Cloud | Aureole radius | Droplet size (mm.) | Second red ring radius | Droplet size (mm.) |
|---|---|---|---|---|
| *A* | 13 ± 1 | 0·012 ± 0·001 | — | — |
| *B* | 6 ± 1 | 0·025 ± 0·004 | 12½ ± 1 | 0·022 ± 0·002 |
| *B* | 7 ± 1 | 0·022 ± 0·004 | — | — |

In addition to the error due to the crudity of the measurements, the finite diameter of the moon introduces an uncertainty about which little appears to be known.

# RESEARCH ITEMS

### Irish Fisheries

Continuing his researches on Irish freshwater fisheries Arthur E. J. Went has published a further study of the sea trout of the Waterville (Currane) River (*Sci. Proc. Roy. Dublin Soc.*, **23** (N.S.), No. 20; 1944), following the work of Went and Barker (1943). It was found in the latter report that the calculated smolt-length of the spring-running sea trout was exceedingly high and the question arose as to whether the later-running smolts had similar high mean lengths, and if so whether these were taken inadvertently by anglers before their descent to the sea in the belief that they were small adult sea trout. It is found by examining new material that the spring-running fish are merely part of the general stocks of sea trout in the Waterville River system and not different from the late-running fish. The rapid growth in fresh water and the large size attained by the smolts are, more or less, unique so far as sea trout have been investigated to date. A second paper by A. E. J. Went (*Proc. Irish Acad.*, **49**, C, No. 5; May 1944) gives an account of the modes of fishing in the Galway Fishery. In 1942 Mr. Went gave a detailed review of the ownership of the fishery in the same publication (**48**, C, No. 5). In the present work the various fishery methods are described, the sites of the fishing engines and certain other data, in order to make it more or less complete.

### Some Primitive Bony Fish of the Middle Coal Measures

A monograph on the Haplolepidæ, published by T. S. Westoll (*Bull. Amer. Mus. Nat. Hist.*, **83**, 1; 1944), is an important contribution to the analysis of the group of primitive bony fishes included in the Palæoniscidæ. It includes not only an exceptionally complete and detailed account of the superficial anatomy of these fish, but also a most interesting discussion of the functional significance of their peculiarities, and of their possible habitat. The family includes two genera only, one divided into two sub-genera, all being found in the "Middle Coal Measures" of Europe and North America in identical form. Dr. Westoll points out the remarkable fact that in four out of six of the localities in which Haplolepids are found they are accompanied by highly peculiar and specialized amphibians, Nectridia and Asistopoda, which are known from only one other "M. Coal Measure" locality, although they occur unaccompanied by Haplolepids in some six localities of later date. This remarkable association, taken in connexion with the very small size of the fish and Amphibia, raises very interesting consideration of Coal Measure geography. Finally, Dr. Westoll's monograph includes a series of very interesting discussions of the morphology of Actinopterygians in general and the course of evolution of their early members.

### Development of Male Daphnia

D. J. Scourfield has investigated the post-embryonal development of the male of *Daphnia magna* (*J. Quek. Micro. Club*, (4), **1**, No. 6; 1943). Although the development of the female has long been known to a certain extent, this is not the case with the male, and these observations are new. Males are much rarer than females, but the author has obtained the first post-embryonal stage by isolating females until they give off broods of males. This first stage, the so-called neonata, is very like that of the female except for the larger antennules, which are distinctly jointed to the head, and a rounded instead of a pointed rostrum. The changes undergone during the post-embryonal stages (usually four) are significant though small. Perhaps the most interesting point in the life-history is the fact that many species of *Daphnia* hatch while still enclosed in an embryonic cuticle in which the young may swim about for some hours, although not feeding. The shell spine is held between the ventral edges of the valves. Traces of antennæ which are free and traces of claws and setæ seem to show that this represents an embryonic stage (presumably a nauplius) usually passed through before hatching; in this it resembles the embryonic cuticle (pre-zoeal) of the decapod Crustacea, which in all probability also represents a nauplius stage.

### Nutritional Physiology of the Silkworm

In a recent review of Soviet researches on the physiology of the silkworm, S. Y. Demyanovski (*Advances in Modern Biology, Moscow*, **16**, 1; 1943) summarizes some outstanding findings referring to protein metabolism in relation to silk secretion. Tryptase proved to be the chief proteolytic enzyme, while dipeptases and polypeptases are absent, and such proteases as may be introduced with plant food are inhibited by the high *p*H value (9·9–10·1) of the digestive juice. Studies of the digestive process established that the proteolytic activity of the digestive juice can be augmented by the addition to food of saccharose or of fructose, the first increasing that activity by 10–12 per cent and the second by 20–50 per cent. This discovery has important practical implications, since by feeding silkworms on mulberry leaves with the addition of saccharose the weight of the larvæ was increased by 38 per cent, as compared with the controls fed on untreated leaves; the weight of cocoons rose by 12 per cent; the length of silk thread increased by 4·5 per cent, its weight by 19 per cent, the thickness by 7 per cent; and the output of silk was 7·8 per cent above that of controls. These experiments were repeated for four years on a number of varieties of silkworm, with consistent results. The best results were obtained when the ratio of saccharose to fresh leaves was 1·5 per cent by fresh weight; greater amounts of saccharose produced a further increase in the weight of the larvæ and fresh cocoons, but not in the output of silk; additional saccharose appears, however, to result in an increased fertility of the moths.

### Genic Action

C. Stern (*Genetics*, **28**, 441; 1943) has published the first of a series of papers on the phenotypic reactions of *Cubitus interruptus* which affects the veins of *Drosophila melanogaster*. He shows that there is a dosage effect of this gene in that an increase in their number approaches the normal wing type of the wild-type allelomorph. On the other hand, the presence of a wild-type allelomorph produces an antagonistic effect when the *ci* gene is increased in number. In such cases the *ci* gene may behave as a dominant instead of as a recessive. The addition of the residue of chromosome IV may also transform *Cubitus interruptus* into a normal phenotype. The author tentatively suggests that each allelomorph has two properties, (1) a combining power, or the degree

of interaction with the substratum, and (2) an efficiency factor which measures the effectiveness of interaction to form the product which is efficient in the elaboration of a normal phenotype. This hypothesis leads to statements regarding the excess or deficiency of combining power and the amount of substratum in relation to the *ci* and wild-type allelomorph.

### Chromosome Numbers in Guayule and Mariola

*Parthenium argentatum*, guayule and *P. incanum*, mariola, have come into prominence as sources of rubber. G. L. Stebbins and M. Kodani (*J. Hered.*, **35**, 163; 1944) have made a cytological examination of strains of these shrubs from various wild sources and of their progenies. There is a large variation in chromosome number; *P. argentatum* had chromosome numbers of 36, 38, 54, 72, 74 and 108–111; *P. incanum* had 54, 72 and 90 chromosomes in the somatic tissue. This large range in polyploidy appears to have a basic chromosome of nine. Plants with 72 chromosomes in *P. argentatum* produce both pseudo haploids (36 chromosomes) and autotriploids (108–111). The fertility and seed fertility bear a relationship to the meiotic irregularities seen in the different polyploid plants. The evolution and relationships of the forms are discussed.

### Combustion Mechanisms and Continuous Spectra in Flames

IN following the details of combustion mechanisms, little information can be got from line spectra. Whereas band spectra are of value in telling us what molecules and radicals are present under flame conditions, still more information about *processes* such as dissociation, ionization and association can be got from studying continuous spectra. The causes and types of continuous spectra emitted by flames have been discussed by A. G. Gaydon (*Proc. Roy. Soc.*, A, **183**, 111; 1944). It is shown that the yellow-green continuous spectrum emitted by some flames containing oxides of nitrogen is probably identical with the spectrum of the air afterglow and is therefore due to a reaction between nitric oxide and atomic oxygen. The presence of atomic oxygen in a flame can therefore be tested by admitting nitric oxide and observing if a yellow-green emission results. For the carbon monoxide flame there appears to be a high concentration of atomic oxygen, both for the dry and moist flame. The combustion mechanism is discussed in detail using this knowledge. For the hydrogen flame a little atomic oxygen is present, but results do not permit of definite conclusions. For hydrocarbon flames there is no sign of atomic oxygen in the inner cone, and this is taken as strong evidence in favour of a peroxide rather than a hydroxylation mechanism.

### Existence of Ammonium Hydroxide

THE question whether ammonium hydroxide really is present in aqueous solutions of ammonia has frequently been raised and some chemists hold that its existence has never been definitely proved. Both Walker in 1903 and Blackman in 1907 adduced evidence, based upon conductivity measurements, in support of the view that ammonium hydroxide was present in relatively small concentrations, and the matter has again been investigated by Briegleb (*Naturwiss.*, **30**, 506; 1942), who sought to discover (1) how ammonia is bound with water in solution, and (2) whether ammonium hydroxide does exist and, if so, whether it is a strong or weak base. In the gas phase the heat of reaction

$$NH_3 + H_2O = NH_4OH$$

was found from proton affinity and polarization methods to be $-$ 49 kcal., if the intramolar distance is 2·5 A. If it is 3 A. then the heat absorbed is 74 kcal. This strongly endothermic reaction is taken to prove that ammonium hydroxide does not exist in the gaseous state. The heat of formation of aqueous ammonium hydroxide is calculated at $-$ 30 (or $-$ 50) kcal., while the heat of reaction

$$NH_3 + H_2O = NH_4^{+}aq. + OH^{-}aq.$$

was found to be between $-$ 1·5 to $-$ 2·0 kcal. The experimental evidence also points to the existence of the hydrates $NH_3,H_2O$ and $2NH_3,H_2O$ with but little formation of $NH_4OH$, which would therefore be almost completely dissociated into ammonium and hydroxyl ions. The thermochemical data are said to accord with observed Raman effects and it is equally evident that ammonium hydroxide is a strong base. The evolution of ammonia from ammonium salts by stronger bases, the neutralization of acids by solutions of ammonia and the hydrolysis of ammonium salts are all explicable, according to Briegleb, in terms of proton affinity.

### Peculiar Stars

GEORGE H. HERBIG has an article with the above title in Leaflet No. 182, April 1944, of the Astronomical Society of the Pacific. He deals with a number of abnormal stars such as ε Aurigae, ζ Aurigae, β Lyrae, etc., and gives a brief outline of the most recent theories advanced to explain these freakish stars. In the case of ε Aurigae we now regard it as a hot, yellowish-white giant accompanied by a huge dim star which is invisible, and which has a diameter 2,700 times that of the sun. Its surface temperature is about 2,000° F., and hence most of its radiation must lie in the infra-red. The β Lyrae system is composed of two giant stars distorted by their mutual gravitation into egg-shaped bodies, their period of revolution around their common centre of gravity being 12 days. An incandescent torrent of gas pours from the larger star, and passing round the smaller one, is ejected into space, where it forms a gigantic expanding pin-wheel about the system. The variable star RW Tauri is a most remarkable system. The smaller white component is hotter and brighter than the larger, cooler, orange companion, and owing to the inclination of their orbit to our line of sight, the principal eclipse is total. Using the 100-in. telescope at Mount Wilson, A. H. Joy has obtained results which indicate the presence of an extended gaseous ring above the equatorial regions of the smaller, brighter star. This suggests an analogy with the rings of Saturn, though a difference arises from the fact that the ring of the RW system is gaseous. The diameter of the ring is about four times that of the sun and its orbital velocity is two hundred miles a second. When the larger star has just covered the disk of the smaller one an edge of the glowing ring is visible for a short time. The question of the existence of such appendages in other stars arises, and it is owing to the relative sizes of the components of RW Tauri and the orbital tilt that the ring has been detected. It is very probable that other stars have similar rings, and if so, some new and interesting problems confront the astronomer.

# ANOMALOUS DISINTEGRATION OF NUCLEI BY COSMIC RAYS

By PROF. A. JDANOV
Radium Institute, Academy of Sciences of the U.S.S.R.

As is well known[1], one effective method for the observation of the disintegration of atomic nuclei by cosmic rays is the method of the 'thick-layer' photographic plates suggested and developed in the Radium Institute of the Academy of Sciences of the U.S.S.R.[2]. The tracks of these disintegrations in such plates are mostly in the form of forks with irregular angular distribution ('stars'). They correspond chiefly to protons, more seldom to $\alpha$-particles and still more seldom to particles with a stronger 'ionization power'. The 'yield' of nuclear disintegrations at sea-level is approximately $8 \times 10^{-3}$ disintegrations in an hour per 1 cm.$^2$ of the area of the plate. This yield rapidly increases with height, reaching a value fifty times greater at a height of 7,000 metres[3]. At sea-level the greatest percentage of disintegrations corresponds to the triple forks. Forks with five tracks are met comparatively seldom, and only with the increase of height is the slow increase of the number of ejected particles in one disintegration observed. In addition to the disintegrations in the form of stars, there are observed also disintegrations in the form of 'showers', that is, in the form of forks with a pronounced unilateral direction of tracks (inside the narrow solid angle). Tracks in the showers may belong to protons as well as to mesotrons. We suggested in previous papers[4] the possibility of the registration of slow mesotrons in the 'thick-layer' plates, and also the possibility of estimating their mass from the average distance between two neighbouring developed grains. In one of our papers[5] there was shown a shower consisting of about a hundred heavy particles, which was obtained on a plate exposed at a height of about 9,000 metres.

At the end of November 1942 we observed[6] the anomalous 'yield' of nuclear disintegrations; here and there on several plates this yield exceeds by $10^3$ times the normal value ($10^{-3}$). (We take account only of those disintegrations and single tracks for which the range is more than 10 cm. of air equivalent.) Just about the same time we succeeded in registering a series of the showers at sea-level. These showers are probably in many cases the complete disintegration of a nucleus into all its components. Such disintegration may be called an 'anomalous' one. Below are given the description and the results of the measurements of two showers, photographs of which are shown in Figs. 1 and 2 (stereomicrophotographs). In Fig. 3 the energy spectra of protons are shown; the number of tracks is plotted against the energy in MeV. at intervals of 0·5 MeV. (positions of separate tracks are indicated by points). The first shower consists of 35 tracks, all corresponding to protons, and it is quite natural to attribute it to the anomalous disintegration of the nucleus of bromine in the photographic emulsion. Measurement of the ranges gives the total energy of protons as $\Sigma E_H \sim 80$ MeV. Assuming that the emitted neutrons have on the average the same energy as protons and taking into account the binding energy of the nucleus $\Delta M \sim 8{\cdot}5\,A$ MeV., where $A$ is the mass number, we obtain for the minimal energy of the incident particle $E_N = \Sigma E_n + \Sigma E_n + \Delta M \sim 900$ MeV.

It is of interest also to consider the momentum of all the particles emitted. Measurement shows that

10 cm. of air equiv.

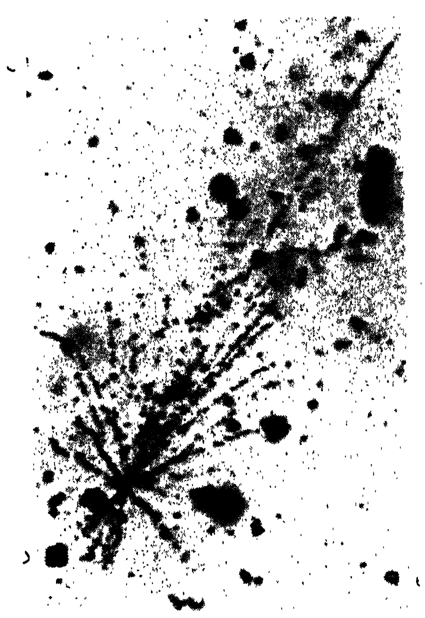

FIG. 1.

10 cm. of air equiv.

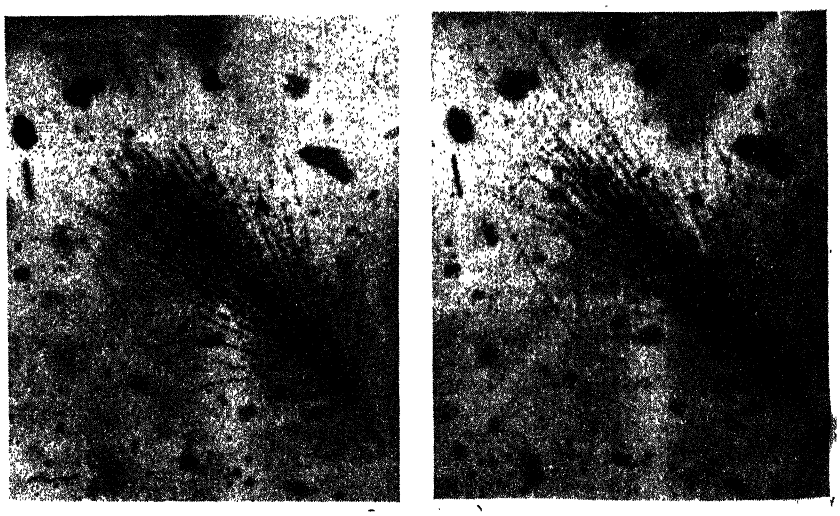

FIG. 2.

the sum of the projections of the momenta of protons on the axis of the shower is $P_H = \Sigma\sqrt{E_H m_H}\cos\alpha = 17{\cdot}6 \sim 20$. Assuming that the total momentum of the neutrons has approximately the same value as that of the protons, we obtain the value of $\sim 40$ for all the particles from nucleus. If we calculate the momentum, $P_N = \sqrt{E_N m_N}$ from the value of the energy of the incident particle, we obtain $P_N \sim 30$ in the case of $m_N = 1$. This number is in satisfactory agreement with the value measured from the photographs.

In the second shower there are about fifty tracks and therefore it is reasonable to consider it as the anomalous disintegration of the silver nucleus. Measurement of the particles of the shower shows that $\Sigma E_H \sim 150$ and $P_H = \sim 70$. In this case the minimum energy of the incident particle is $E_N \sim 1{,}300$ MeV. and $P_N \sim 35$ (for $m_N = 1$).

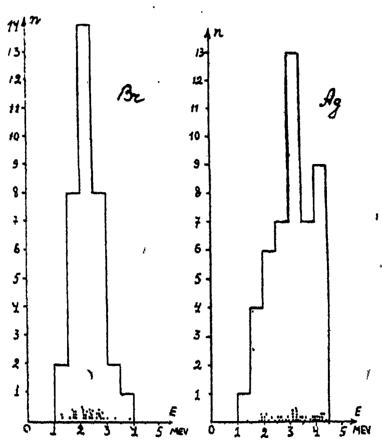

FIG. 3.

It should be noticed that $P_N$ is in both cases somewhat less than $P_H + P_n$.

If the disintegrations were due to photons, electrons or even to mesotrons, the momentum would have quite another order of magnitude. It is interesting to notice that all the particles in the showers are emitted within a cone the cross-section of which is a very eccentric ellipse. For example, in our cases the ratios of the axes of the ellipses are $0{\cdot}13$ and $0{\cdot}15$, and for the shower described in the previous paper[5] is $0{\cdot}1$. This eccentricity of disintegrations can be explained by the fact that the collision between the cosmic particles and the nucleus is non-central.

Thus the existence of the showers shows the presence of heavy particles of mass $m \simeq 1$ and energy $\sim 10^9$ eV. in the cosmic radiation at sea-level.

Further details and examples of anomalous disintegration of nuclei will be submitted to the *Physical Review*.

# INDIAN FOREST WAR-TIME PRODUCTS

WHEN Lord Curzon, Viceroy of India, sanctioned in 1906 the institution of a Forest Research Institute, with headquarters at Dehra Dun, even so wide-visioned a man as he could not have anticipated the great benefits it was to confer on India. Even during the War of 1914–18 the imports into India of what had previously been deemed necessaries of life were curtailed, and forest research at once stepped into the breach and by the close of that War had not only established its position but had outgrown all the buildings, equipment and so forth for which provision was made by 1914, although it was considered sufficient for the next score of years. A great new building and much additional equipment was sanctioned by 1920 and has long been functioning. During the present War, in some directions the Institute has been able to answer urgent imperative calls of both Army and public. Curiously enough, although the chief branches of forestry were catered for, including utilization, which assumes such an important place in war-time, it was not until comparatively late in its existence that the importance of the minor products of the Indian forests, admittedly a sub-branch of utilization, received due recognition at the Institute—or perhaps at the hands of Government—a special branch being at length formed which has proved of the very highest value, especially in combination with the Chemical Branch, during the present War. Some of this work has already been noted in these columns. Two *Indian Forest Leaflets*, Nos. 60 and 64, Sylviculture (Forest Research Institute, Dehra Dun, 1944), issued recently, deal with two further products of the Indian forest.

No. 60 is entitled "Short Note of the Beedi Leaf Industry". Beedis are locally made Indian cigarettes with leaf wrappers. As an article of merchandise the industry is believed to have started between 1905 and 1916 in different parts of India, chiefly in Bihar, the Central Provinces, the Eastern States and Patna. The traditional smoke of the Indian is the hookha and chilam. For purely agricultural pursuits the hookha is not an encumbrance, but it is difficult to carry about, and the chilam is a fragile article. With increased industrialism and faster travel by rail and motor-car, the need for a cheap and more portable smoke was met by the cheap foreign cigarette. Supplies of these became difficult to obtain during the War of 1914–18, and the beedi began to become known. The use of leaves of local tree species for making pipes was a common practice of many tribes; it was a short step therefrom to using leaves for preparing cheap cigarettes, and the present War has given a great impetus to this manufacture, expanding industry and the great increase in the Indian Army being two important factors.

The leaves of many indigenous plants are used for wrapping tobacco in, but *Diospyros Melanoxylon* is the one generally preferred owing to its peculiar flavour, flexibility in texture and resistance to early decay. It occurs in the southern two thirds of India proper from, roughly, an east and west line approximately a hundred miles to the north of Calcutta. Other leaves used are those of *Bauhinia racemosa* and *B. vahlii*, *Butea frondosa*, *Castanopsis indica* and *Shorea robusta*. The supply of the leaves is eminently a forestry industry, and the best methods of obtaining the maximum crop of leaves, whether

by pollarding, coppicing or root-suckers, are being closely investigated. The pamphlet deals with the financial and industrial aspects, period of collection of the leaves and grading, drying, still under experiment, storage, packing and transport.

Leaflet No. 64, on "The Growing of *Cryptostegia grandiflora* as a War-time Emergency Crop", describes another and more important war-time object, namely, the production of rubber. *Cryptostegia grandiflora* is indigenous to Madagascar and probably to Africa. The plant is described as a scrambler; it grows erect until about 1½ ft. high and then it climbs and scrambles until after some years it can again stand by itself. It is therefore greatly helped in its early development if it has something to climb on. It was imported into India many years ago as a garden plant for its flowers. It has since run wild in many places, generally in arid or semi-arid climates; for example, Kalka near Delhi, Muttra near Poona, Hyderabad (Sind), etc., with a rainfall of 5–25 in. and elevations up to 1,500 ft. In such situations it was noticed that the best development occurred on land subject to local inundations, but it obviously could withstand arid conditions. A survey by the Indian Agricultural Research Institute revealed the fact that it was present in all parts of India in various soils; namely, black, brown, red, laterite, Indo-Gangetic alluvium, sands, clays, acid and alkaline soils; in all climates without regard to temperature, rainfall, humidity, light, wind and exposure; on river banks and where the subsoil water table is high—an amazing power of adaptation. It is considered probable that a well-drained fertile soil with a gentle slope at about 1,000 ft. elevation and a rainfall of 60 in. will suit it best, particularly if it can be irrigated during periods of dry weather.

Since the Japanese occupation of Malaya and the Dutch East Indies, which deprived the Allies of some 90 per cent of their supplies of raw rubber, much work has been done on the possibilities of developing additional war-time supplies of vegetable rubber. The *Cryptostegia* in question has proved a most promising plant, and in the past eighteen months or so experimental work has been carried out and large-scale experience gained. Most of the publications on this work have been academic rather than practical. The present pamphlet, it is emphasized, only sets out to give the information at present available, based on a year's practice in planting plantations of the plant for the sole purpose of obtaining the maximum production of rubber in the minimum time, the question of costs not being of primary importance. A better plantation technique will be a matter for the future should this type of cultivation be found remunerative after the War. The seed is sown in nurseries and the seedlings put out at the outbreak of the rains when about two months old. They are planted in lines or double lines about 6 ft. apart to allow room for the tapping operations to be undertaken. Each row has a simple form of fence 4 ft. 6 in. high on which the plants can climb. Since the object is to obtain maximum results in the shortest time, dense planting is necessary. "Tapping," it is said, "has of necessity to be of a few shoots per bush; therefore we have to grow these shoots at such a height and by such an arrangement that the labour can tap as many shoots as possible in the smallest area with the minimum of trouble."

The pamphlet gives full details of all the operations necessary to form a plantation and to exploit it, but emphasizes the fact that the methods at present employed are the results of, and therefore to some extent due to, the fact that during the past year it has been a 'rush-job'. From the descriptions given of the work it seems to be very satisfactory, and to reflect great credit on the careful research work which has enabled it to be carried out at so critical a time for the Allies' rubber resources.

## FLINT KNAPPING
